## Example Problem - Le 15

Ex. The wheel rolls up the incline on its hubs without slipping and is pulled by the $100-\mathrm{N}$ force applied to the cord wrapped around its outer rim. If the wheel start from rest, compute its angular velocity after its center has moved a distance of 3-m up the incline. The wheel has a mass of $40-\mathrm{kg}$ with a center of mass at O and has a centroidal radius of gyration of $150-\mathrm{mm}$. (taken from Engineering Mechanics, 4th Edition by Meriam \& Kraige)
