Name:										

Use this quiz to help make sure you understand the videos/reading. **Answer all questions.** Make additional notes as desired. **Not sure of an answer?** Ask your instructor to explain in class and revise as needed then.

Throughout, where you are asked to "circle your choice", you can circle or underline it (whichever you prefer).

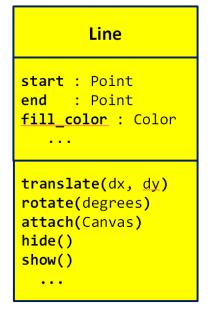

Video: Classes - The Concepts

1. The diagrams to the right are called

____ Class Diagrams, where
____ stands for Unified Modeling
Language. (Fill in both blanks with the
(same) 3-letter acronym for **U**nified **M**odeling **L**anguage.)

2. Consider the 2 UML class diagrams shown above and to the right. What are the names of the two *classes* shown?

Point x : int y : int ... move(dx, dy) reflect(Line) attach(Canvas) ...

- 3. Consider the UML class diagram for the **Point** class shown above. For that class:
 - a. What are the names of the two instance variables (fields) that are shown?
 - b. What do you think that those fields represent? (You can't tell this authoritatively from the UML class diagram; just make your best guess based on the names of the fields.)
 - c. How many **methods** are shown?
 - d. How many parameters does the *move* method require?
 - e. How many parameters does the *reflect* method require?
 - f. How many parameters does the *attach* method require?
 - g. What kind of thing is the **reflect** method's parameter?
 - h. What kind of thing is the *attach* method's parameter?

- 4. Consider the UML class diagram for the *Line* class shown above. For that class:
 - a. What are the names of the three instance variables (fields) that are shown?
 - b. What do you think that those fields represent? (You can't tell this authoritatively from the UML class diagram; just make your best guess based on the names of the fields.)
 - c. How many **methods** are shown?
 - d. How many parameters does the *translate* method require?
 - e. How many parameters does the *hide* method require?
- 5. True or false: A single class can have many instances of that class. **True False** (circle your choice)
- 6. True or false: For any particular class (say, the Point class), any instance of that class uses the same **NAMES** for its *instance variables* as any *other* instance of that class. **True False** (circle your choice)
- 7. Consider two objects **alpha** and **beta**, both of which are instances of the same class. Suppose that both have an instance variable called **time_of_day**. True or false: The VALUE of **alpha's time_of_day** is necessarily the same as the VALUE of **beta's time of day**. **True False** (circle your choice)
- 8. True or false: For any particular class (say, the Point class), any instance of that class uses the same **NAMES** for its **methods** as any **other** instance of that class. **True False** (circle your choice)
- 9. Consider two objects alpha and beta, both of which are instances of the same class. Suppose that both have a method called sick_days_left() that returns a number. True or false: The value returned by a call to alpha's sick_days_left() is necessarily the same as the value returned by a call to beta's sick_days_left().
 True False (circle your choice)

Video: Classes - Notation

In the following questions, we are referring to Point and Line classes per the UML class diagrams shown below that are NOT part of RoseGraphics. That is why **you will not see (and should not put) any "rg dots".**

10. The following examples show two different attempts by two students to construct a new Point at (4, 3). Based on what you learned about constructing objects in Python, which student is correct and why?

```
# Anna
point_anna = Point
point_anna.x = 4
point_anna.y = 3

# Dalton
point_dalton = Point(0,0)
point_dalton.x = 4
point_dalton.y = 3
```

x : int
y : int
...

move(dx, dy)
reflect(Line)
attach(Canvas)
...

Point

11. A Point's constructor takes an initial x and a y. Thus, both of the above examples are needlessly long. How would you instead construct the point using just **one** line of code?

(continues on the next page)

13. Suppose you are told that a Line's constructor takes a start and end point as its constructor arguments, as suggested by the UML class diagram to the right. What line of code would you write to create a Line between a point called *point_mine* and a *new Point* at (0, 5), putting the constructed object into a variable called *line1*.

14. Assuming that you have a third Point called *another_point*, write the statement that would cause the Point class' **reflect** method to **reflect another_point** about the Line constructed in the previous question:

a. Assuming that the **reflect** method RETURNS a new Point that is the reflected point?

Line

start : Point
end : Point
fill_color : Color

. . .

translate(dx, dy)
rotate(degrees)
attach(Canvas)
hide()
show()

b. Assuming that the **reflect** method MODIFIES its Point to be reflected about the given Line?

15. Suppose that you have two *Line* objects s in variables *Line1* and *Line2*, respectively. Write statements that set *Line1*'s fill color to 'red' and *Line2*'s fill color to 'blue'.

<u>Video: Classes – Implementation</u>

16.	Write the complete definition of a class called	Dog	that (so far) has nothing and does
	nothing.		

17. What is the name of the special method of the **RoseWindow** class that is called by the following statement:

```
window = rg.RoseWindow()
```

18. Suppose that you have a class called **Dog** that has the following **__init**__ method:

```
class Dog(object):

   def __init__(self, dog_name, age):
        self.name = dog_name
        self.age = age
```

When the following statements run, what will **dog_name** and **age** be set to when **__init__** is running?

- a. fido = Dog('buster', 3)

 dog_name is set to _____ age is set to _____

19. Continuing the previous problem, what does each of the following PRINT statements print (or, if the statement has any error, just write ERROR), given the first two statements:

```
class Dog(object):
    def __init__(self, dog_name, age):
        self.name = dog_name
        self.age = age
```

- 20. Continuing the Dog class example, suppose we added a third line to __init__, as shown to the right.
 - a. Is that last line legal? If so, what is its effect?

```
class Dog(object):
```

```
def __init__(self, dog_name, age):
    self.name = dog_name
    self.age = age
    self.breed = 'poodle'
```

b. If after constructing fido (per a previous problem), a statement included **fido.breed** would that result in an error? If not, what would it evaluate to?

In the video you saw the definition of a **Point** class method called **move_by** that took two arguments and moved the **Point**'s coordinates (**x** and **y** instance variables) by those values. Keeping that example in mind:

21. Write the definition of a **Point** class method called **move_to** that takes two arguments and moves the Point TO (not BY) the given coordinates.

22. Write the definition of a **Point** class method called **clone** that takes NO arguments and returns a **new Point** whose **x** and **y** coordinates are the same as the Point's coordinates.
