

Name: _____ CM: _____ Section: _____ Grade: _____ of 10

1. Show the output of these expressions:

`print(3 + 3)` _____ `print ("3" + "3")` _____

Why are the outputs different?

2. What is the output of the code shown to the right?

```
nums = []
for k in range(5):
    nums = nums + [k * 2]
print(nums)
```

3. Suppose that we modified the code in the preceding problem by replacing the `nums = []` line with `nums = 0` and dropping the `[]` surrounding `k * 2`, so that the code becomes like that shown to the right.

```
nums = 0
for k in range(5):
    nums = nums + k * 2
print(nums)
```

- What is the output of the modified code? _____
- The name (variable) *nums* is now badly chosen. What would be a better name for it?

4. What happens in problem 2 if we forget the `nums = []` line altogether? Be specific.

5. Suppose that we modified the code in the preceding problem yet again, so that it now looks like the code shown to the right.

```
nums = ""
for k in range(5):
    nums = nums + str(k * 2)
print(nums)
```

- What is the output of the modified code?
- What would go wrong if we omitted the `str` function call?

(continues on the back of this page)

7. Suppose that `seq_of_seqs` is a sequence of sequences, for example,

```
[ [1, 2, 3], [4, 5], [6], [7, 8, 9], [] ]
```

Write code that would print the **length** of each inner sequence, each on its own line (so the above example would print `3 2 1 3 0` but each on its own line).

8. Repeat the previous problem, but now looping BACKWARDS from the **last** element in `seq_of_seqs` to the **first** element (so the above example would print `0 3 1 2 3` but each on its own line).

9. The function shown to the right is intended to return **True** if the given sequence of numbers contains a negative number, and **False** otherwise. For example:

`has_negative([5, 3, -4, 8])` should return **True**

`has_negative([5, 3, 4, 8])` should return **False**

- What does *has_negative*, as written, in fact return when the argument is `[5, 3, -4, 8]`?
- Mark up the code to indicate the changes needed to make the code correct.

```
def has_negative(numbers):
    for k in range(len(numbers)):
        if numbers[k] < 0:
            return True
        else:
            return False
```

10. The function shown to the right is intended to return **True** if the given sequence of numbers is a *decreasing* sequence, that is, if each number in the sequence is less than or equal to the *next* number in the sequence. For example:

`is_decreasing([15, 11, 4, 4, 1])`
should return **True**

`is_decreasing([15, 11, 4, 8, 1])`
should return **False** (since 8 is bigger than 4, its predecessor in the sequence).

- Fill in the blanks with **True** and **False** in the appropriate places.
- The function has a small error in the FOR statement. Mark up the code to correct the error.

```
def is_decreasing(numbers):

    for k in range(len(numbers)):

        if numbers[k + 1] > numbers[k]:

            return _____

    return _____
```
