CSSE 230

Quicksort algorithm
Average case analysis

After today, you should be able to…
…implement quicksort
…derive the average case runtime of quick sort and similar algorithms

INEFFECTIVE SORTS

```
DEFINE HALFHEARTEDMERGESORT(LIST):
    IF LENGTH(LIST) < 2:
        RETURN LIST
    PIVOT = INT(LENGTH(LIST) / 2)
    A = HALFHEARTEDMERGESORT(LIST[:PIVOT])
    B = HALFHEARTEDMERGESORT(LIST[PIVOT:])
    // UMMMMM
    RETURN [A, B] // HERE. SORRY.
```

```
DEFINE FASTBOGOSORT(LIST):
    // AN OPTIMIZED BOGOSORT
    // RUNS IN O(N LOG N)
    FOR N FROM 1 TO LOG(LENGTH(LIST)):
        SHUFFLE(LIST):
        IF ISSORTED(LIST):
            RETURN LIST
    RETURN "KERNEL PAGE FAULT (ERROR CODE: 2)"
```

```
DEFINE JOBINTERVIEWQUICKSORT(LIST):
    OK SO YOU CHOOSE A PIVOT
    THEN DIVIDE THE LIST IN HALF
    FOR EACH HALF:
        CHECK TO SEE IF IT'S SORTED
            NO, WAIT, IT DOESN'T MATTER
        COMPARE EACH ELEMENT TO THE PIVOT
            THE BIGGER ONES GO IN A NEW LIST
            THE EQUAL ONES GO INTO, UH
            THE SECOND LIST FROM BEFORE
        HANG ON, LET ME NAME THE LISTS
            THIS IS LIST A
            THE NEW ONE IS LIST B
        PUT THE BIG ONES INTO LIST B
        NOW TAKE THE SECOND LIST
            CALL IT LIST, UH, A2
        WHICH ONE WAS THE PIVOT IN?
        SCRATCH ALL THAT
        IT JUST RECURSIVELY CALLS ITSELF
        UNTIL BOTH LISTS ARE EMPTY
            RIGHT?
        NOT EMPTY, BUT YOU KNOW WHAT I MEAN
    AM I ALLOWED TO USE THE STANDARD LIBRARIES?
```

```
DEFINE PANICSORT(LIST):
    IF ISSORTED(LIST):
        RETURN LIST
    FOR N FROM 1 TO 10000:
        PIVOT = RANDOM(0, LENGTH(LIST))
        LIST = LIST[PIVOT:] + LIST[:PIVOT]
        IF ISSORTED(LIST):
            RETURN LIST
    IF ISSORTED(LIST):
        RETURN LIST:
    IF ISSORTED(LIST):  //THIS CAN'T BE HAPPENING
        RETURN LIST
    IF ISSORTED(LIST): //COME ON COME ON
        RETURN LIST
    // OH JEEZ
    // I'M GONNA BE IN SO MUCH TROUBLE
    LIST = [ ]
    SYSTEM("SHUTDOWN -H +5")
    SYSTEM("RM -RF ./")
    SYSTEM("RM -RF ~/*")
    SYSTEM("RM -RF /")
    SYSTEM("RD /S /Q C:\*")  //PORTABILITY
    RETURN [1, 2, 3, 4, 5]
```

Stacksort connects to StackOverflow, searches for "sort a list", and downloads and runs code snippets until the list is sorted.

Review: The Master Theorem works for divide-and-conquer recurrence relations only ... but works well!

For any recurrence relation *in the form*:

$$T(N) = aT\left(\frac{N}{b}\right) + \theta\left(N^k\right), with\ a \geq 1, b > 1$$

The solution is:

$$T(N) = \begin{cases} \theta(N^{log_b a}) & if\ a > b^k \\ \theta(N^k log N) & if\ a = b^k \\ \theta(N^k) & if\ a < b^k \end{cases}$$

Theorem 7.5 in Weiss

Sorting Demos

  - http://maven.smith.edu/~thiebaut/java/sort/demo.html
  - http://www.cs.ubc.ca/~harrison/Java/sorting-demo.html

QuickSort (a.k.a. "partition-exchange sort")

- Invented by C.A.R. "Tony" Hoare in 1961*
- Very widely used
- Somewhat complex, but fairly easy to understand
  - Like in basketball, it's all about planting a good pivot.

A quote from Tony Hoare:
There are two ways of constructing a software design: One way is to make it so simple that there are obviously no deficiencies, and the other way is to make it so complicated that there are no obvious deficiencies. The first method is far more difficult.
Image from http://www.ultimate-youth-basketball-guide.com/pivot-foot.html.

Partition: split the array into 2 parts: smaller than pivot and greater than pivot
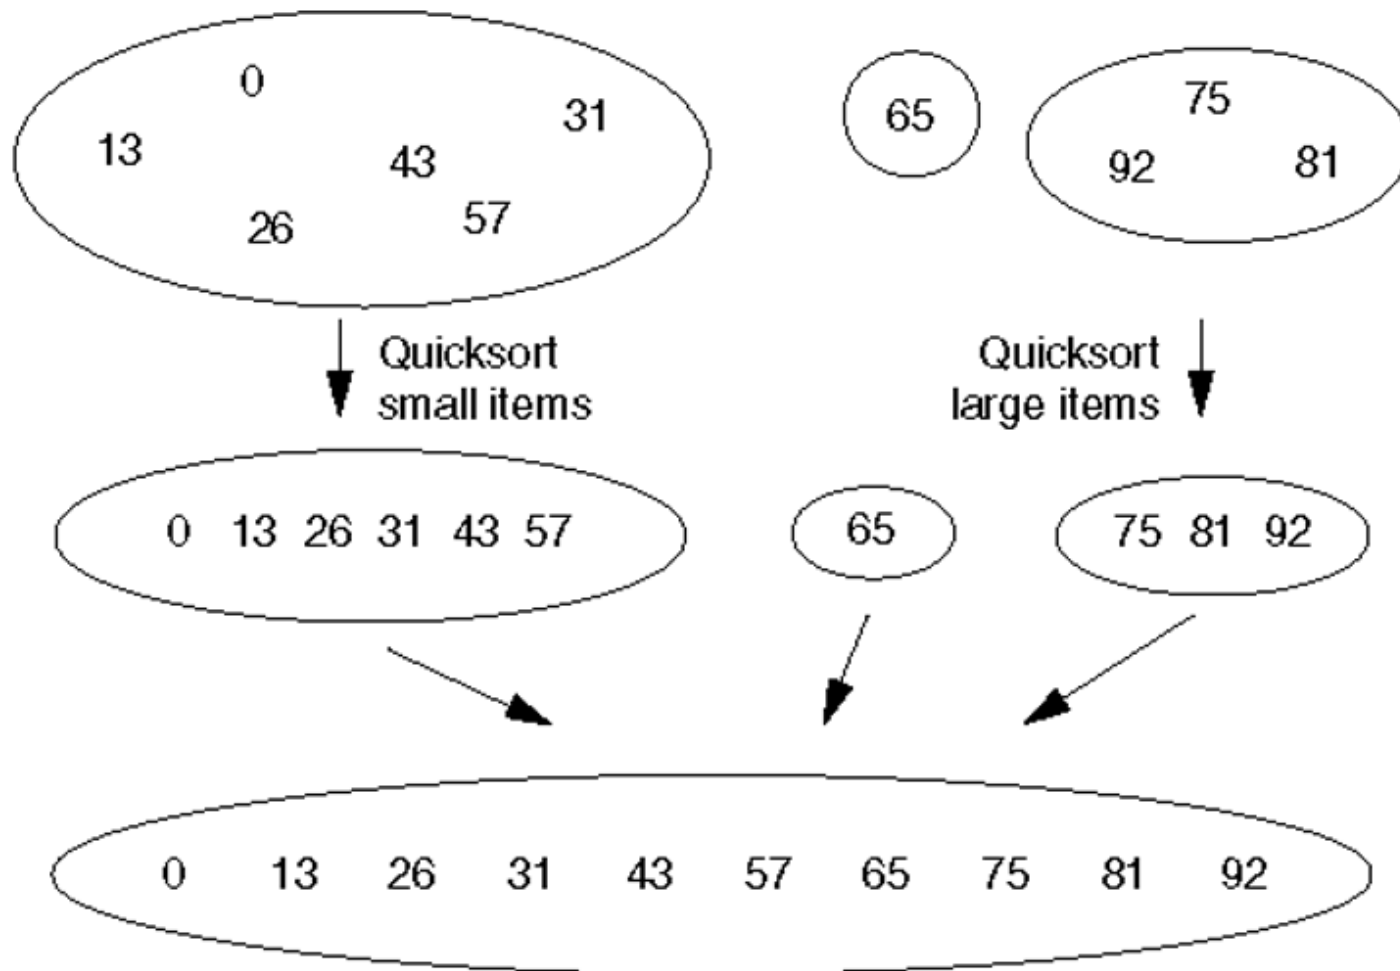

Quicksort then recursively calls itself on the partitions

Partition: efficiently move small elements to the left of the pivot and greater ones to the right

```
// Assume min and max indices are low and high
pivot = a[low] // can do better
i = low+1, j = high
while (true) {
  while (a[i] < pivot) i++
  while (a[j] > pivot) j--
  if (i >= j) break
  swap(a, i, j)
}
swap(a, low, j) // moves the pivot to the
          // correct place
return j
```

QuickSort Average Case

- Running time for partition **of N elements** is $\Theta(N)$
- Quicksort Running time:
  - call partition. Get two subarrays of sizes N_L and N_R (what is the relationship between N_L, N_R, and N?)
  - Then Quicksort the smaller parts
  - $T(N) = N + T(N_L) + T(N_R)$
- Quicksort Best case: write and solve the recurrence
- Quicksort Worst case: write and solve the recurrence
- average: a little bit trickier
  - We have to be careful how we measure

Average time for Quicksort

- Let T(N) be the average # of comparisons of array elements needed to quicksort N elements.

- What is T(0)? T(1)?

- Otherwise T(N) is the sum of
  - time for partition
  - average time to quicksort left part: $T(N_L)$
  - average time to quicksort right part: $T(N_R)$

- $T(N) = N + T(N_L) + T(N_R)$

We need to figure out for each case, and average all of the cases

▸ Weiss shows how *not* to count it:

▸ What if half of the time we picked the smallest element as the partitioning element and the other half of the time we picked the largest?

▸ Then on the average, $N_L = N/2$ and $N_R = N/2$,

  ◦ but that doesn't give a true picture of these worst-case scenarios.

  ◦ In every case, either $N_L = N-1$ or $N_R = N-1$

We assume that all positions for the pivot are equally likely

▸ We always need to make some kind of "distribution" assumptions when we figure out Average case

▸ When we execute

    `k = partition(pivot, i, j),`

all positions i..j are equally likely places for the pivot to end up

▸ Thus N_L is equally likely to have each of the values 0, 1, 2, … N−1

▸ $N_L + N_R = N-1$; thus N_R is also equally likely to have each of the values 0, 1, 2, … N−1

▸ Thus $T(N_L) = T(N_R) =$

Continue the calculation

▸ T(N) =

▸ Multiply both sides by N

▸ Rewrite, substituting N−1 for N

▸ Subtract the equations and forget the insignificant (in terms of big-oh) −1:

  ◦ NT(N) = (N+1)T(N−1) + 2N

▸ Can we rearrange so that we can telescope?

Continue continuing the calculation

▸ NT(N) = (N+1)T(N−1) + 2N

▸ Divide both sides by N(N+1)

▸ Write formulas for T(N), T(N−1),T(N−2) …T(2).

▸ Add the terms and rearrange.

▸ Notice the familiar series

▸ Multiply both sides by N+1.

Recap

- Best, worst, average time for Quicksort
- What causes the worst case?

- We can guarantee we never hit the worst case
  - How?
  - But this makes quicksort slower than merge sort in practice.

Improvements to QuickSort

- Avoid the worst case
  - Select pivot from the middle
  - Randomly select pivot
  - **Median of 3 pivot selection. (You'll want this.)**
  - Median of k pivot selection
- "Switch over" to a simpler sorting method (insertion) when the subarray size gets small

  Weiss's code does Median of 3 and switchover to insertion sort at 10.
  - Linked from schedule page

  What does the official Java Quicksort do? See the source code!

Final notes

The partition code given earlier has 2 problems:
1. Can walk off the end of the array
2. If the chosen pivot is duplicated, can go into an infinite recursion

```
// Assume min and max indices are low and high
pivot = a[low] // can do better
i = low+1, j = high
while (true) {
  while (a[i] < pivot) i++
  while (a[j] > pivot) j--
  if (i >= j) break
  swap(a, i, j)
}
swap(a, low, j)    // moves the pivot to the
                   // correct place
return j
```
