# CSSE 230 Day 4

#### Maximum Contiguous Subsequence Sum

After today's class you will be able to:

provide an example where an insightful algorithm can be much more efficient than a naive one.

#### Announcements

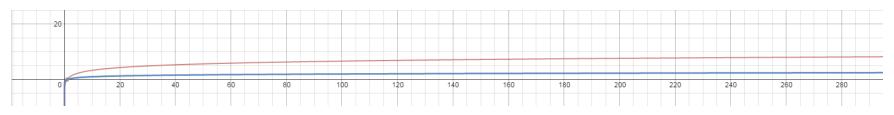

- Sit with your StacksAndQueues partner now
- Why Math?

#### HW2

- Recommended: complete #1 (UML Diagram of Collections) by next class, as we will discuss Collections
- You should be ready to work on all of the problems

#### Homework 2

- Is it true that  $log_a(n)$  is  $\theta(log_b(n))$ ?
- Complete homework 2 to find out the exciting conclusion!
- Here is the graph for a=2 and b=10:

#### • Is it true that $3^n$ is $\theta(2^n)$ ?

Andrew Hettlinger ► Matt Boutell November 6 at 12:30pm - 444

In your class, I never thought I'd actually use big O notation, but now I find myself using it in my complaints to coworkers about how a previous developer would sort a list before doing a binary search to find a single element O(nlogn) + O(logn) instead of just doing a linear search O(n). I feel really nerdy now (as if I didn't before 🙂 )

Like · Comment

So why would we ever sort first to do binary search?

#### Recap: MCSS

Problem definition: given a nonempty sequence of *n* (possibly negative) integers A<sub>0</sub>, A<sub>1</sub>, A<sub>2</sub>, ..., A<sub>n-1</sub>, find the maximum contiguous subsequence

$$S_{i,j} = \sum_{k=i}^{j} A_k$$

and the corresponding values of *i* and *j*.

# Recap: Eliminate the most obvious $Q^3$ inefficiency, get $\Theta(N^2)$

```
for( int i = 0; i < a.length; i++ ) {</pre>
      int thisSum = 0;
      for (int j = i; j < a.length; j++) {
          thisSum += a[ j ];
          if( thisSum > maxSum ) {
              maxSum = thisSum;
              segStart = i;
              seqEnd = j;
          }
      }
 }
Exhaustive search: find every S<sub>i,i</sub>
```

#### MCSS is O(n<sup>2</sup>)

#### Is MCSS θ(n<sup>2</sup>)?

- Showing that a problem is Ω (g(n)) is much tougher. How do you prove that it is impossible to solve a problem more quickly than you already can?
- Can we find a yet faster algorithm?
  - If so, it can't use exhaustive search. (Why?)

f(n) is O(g(n)) if f(n) ≤ cg(n) for all n ≥ n<sub>0</sub>
So O gives an upper bound
f(n) is Ω(g(n)) if f(n) ≥ cg(n) for all n ≥ n<sub>0</sub>
So Ω gives a lower bound
f(n) is θ(g(n)) if c<sub>1</sub>g(n) ≤ f(n) ≤ c<sub>2</sub>g(n) for all n ≥ n<sub>0</sub>
So θ gives a tight bound
f(n) is θ(g(n)) if it is both O(g(n)) and Ω(g(n))

#### **Observations?**

▶ Consider {1, 4, -2, 3, -8, 4, -6, 5, -2}

Any subsequences you can safely ignore?
 Discuss with another student (1.5 minutes)

## **Observation** 1

- We noted that a max-sum sequence S<sub>i,j</sub> cannot begin with a negative number.
- Generalizing this, it cannot begin with a prefix S<sub>i,k</sub> with k<j whose sum is negative.</p>
  - Proof by contradiction. Suppose that S<sub>i,j</sub> is a max– sum sequence and that S<sub>i,k</sub> is negative. In that case, a larger–sum contiguous sequence can be created by removing S<sub>i,k</sub>. However, this violates our assumption that S<sub>i,j</sub> is a max–sum contiguous sequence.

## **Observation 2**

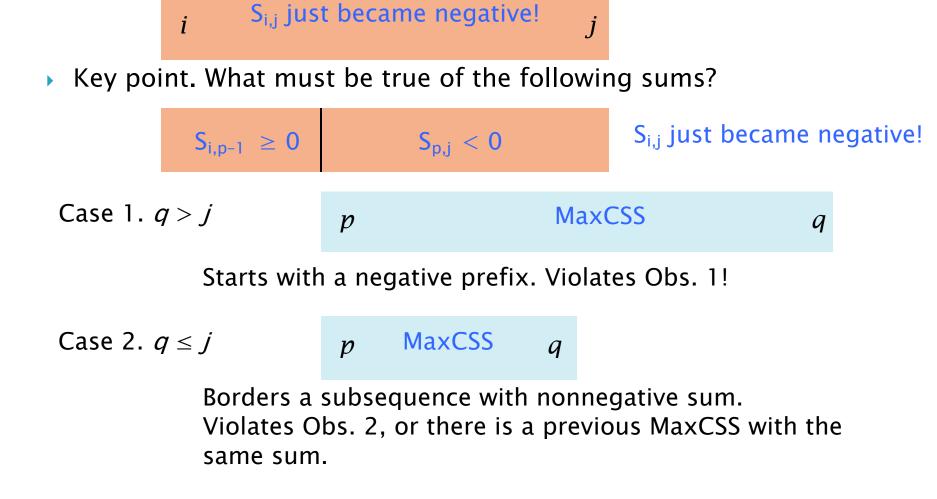

- Every contiguous subsequence that borders a maximum contiguous subsequence must have a negative or zero sum.
  - Proof by contradiction. Consider a contiguous subsequence that borders an MCSS sequence. Suppose it has a positive sum. We can then create a larger max-sum sequence by combining the two adjacent sequences. This contradicts our assumption that the original sequence has the maximum sum.

## **Observation 3**

- Imagine we are growing subsequences from a fixed left index *i*. That is, we compute the sums S<sub>i,j</sub> for increasing *j*.
- Claim: If there is such an S<sub>i,j</sub> that "just became negative" (for the first time, with the inclusion of the J<sup>th</sup> term), any subsequence starting in between i + 1 and j cannot be a MaxCSS (unless its sum equals an already-found MaxCSS)!
- In other words, as soon as we find that S<sub>i,j</sub> is negative, we can skip all sums that begin with any of A<sub>i+1</sub>, ..., A<sub>j</sub>.
- I.e., we can "skip *i* ahead" to be j + 1.

## Proof of Observation 3

> Proof by Contradiction. Suppose there is such a MaxCSS, namely  $S_{p,q},$  where  $i+1 \leq p \leq j.$ 

## New, improved code!

```
public static Result mcssLinear(int[] seq) {
    Result result = new Result();
    result.sum = 0;
    int thisSum = 0;
    int i = 0;
    for (int j = 0; j < seq.length; j++) {</pre>
        thisSum += seq[j];
        if (thisSum > result.sum) {
             result.sum = thisSum;
             result.startIndex = i:
                                               S<sub>i.i</sub> is negative. So,
             result.endIndex = j;
                                                 skip ahead per
        } else if (thisSum < 0) {</pre>
             // advances start to where end
                                                  Observation 3
             // will be on NEXT iteration
             i = j + 1;
             thisSum = 0;
         }
```

return result;

Running time is O (?) How do we know?

#### What have we shown?

- MCSS is O(n)!
- Is MCSS  $\Omega(n)$  and thus  $\theta(n)$ ?
  - Yes, intuitively: we must at least examine all n elements

#### Time Trials!

- From personal repo, checkout MCSSRaces
- Study code in MCSS.main()
- For each algorithm, how large a sequence can you process on your machine in less than 1 second?

#### MCSS Conclusions

- The first algorithm we think of may be a lot worse than the best one for a problem
- Sometimes we need clever ideas to improve it
- Showing that the faster code is correct can require some serious thinking
- Programming is more about careful consideration than fast typing!

#### Interlude

- If GM had kept up with technology like the computer industry has, we would all be driving \$25 cars that got 1000 miles to the gallon.
   Bill Gates
- If the automobile had followed the same development cycle as the computer, a Rolls-Royce would today cost \$100, get a million miles per gallon, and explode once a year, killing everyone inside.

- Robert X. Cringely

#### Interlude

#### Stacks and Queues

A preview of Abstract Data Types and Java Collections

This week's major program

# Stacks and Queues assignment

**Intro:** Ideas for how to implement stacks and queues using arrays and linked lists

How to write your own growable circular queue:

- 1. Grow it as needed (like day 1 exercise)
- 2. Wrap-around the array indices for more efficient dequeuing

# Stacks and Queues implementation

**Analyze** implementation choices for Queues – much more interesting than stacks! (See HW)

**Application:** An exercise in writing cool algorithms that evaluate mathematical expressions:

Evaluate Postfix: 6 7 8 \* + (62. How?) Convert Infix to Postfix: 6 + 7 \* 8 (6 7 8 \* + You'll figure out how)

Both using **stacks**. Read assignment for hints on *how*.

#### Meet your partner

- Plan when you'll be working. We suggest that your first meeting should be today or tomorrow
- Review the pair programming video as needed
- Check out the code and read the specification together
