

CSSE 304 Day 11

1. Question from the previous class: Another procedures that can be shorter if written using list-recur. Instructor's example.
2. Question from the previous class: Which of the 5 procedures that we wrote using list-recur is a bad idea to write that way? Why?
3. Consider the following Scheme transcript (from which I have removed part of the definition) Fill in the missing part. You might want to try it in Scheme to see if your code works.

```
> (define a                  ) ;fill it in!  
> (list ((car a) 4 7)  
        ((cadr a) 4 7))  
(11 28)
```

Recall: Grammar for lambda-calculus expressions:

<LcExpr> ::= <identifier>	variable use
(lambda (<identifier>) <LcExpr>)	abstraction
(<LcExpr> <LcExpr>)	application

4. Use this grammar to derive ((lambda (x) (x y)) z)

Variable x **occurs free** in the LcExp e iff one of the following is true:

F1. e is a variable, and e is the same as x .

F2. e is an abstraction $(\lambda (y) e')$, where y is different from x and x occurs free in e' .

F3. e is an application $(e_1 e_2)$, where x occurs free in e_1 or in e_2 .

Variable x **occurs bound** in the LcExp e iff

one of the following is true:

B1. e is an abstraction $(\lambda (y) e')$, where x occurs bound in e' , **or** x and y are the same variable and x occurs free in e' .

B2. e is an application $(e_1 e_2)$ where x occurs bound in e_1 or in e_2 .

5. Free and bound occurrences of variables. Formal definitions of *occurs free* and *occurs bound* (in box above)
6. **Examples:** In each of the following expressions, does x occur free and/or occur bound?

- x
- t
- $(x\ t)$
- $(\text{lambda } (x) (x\ t))$
- $((\text{lambda } (x) x) x)$
- $(\text{lambda } (x) (\text{lambda } (t) (t\ x)))$

Follow the grammar. **occurs-free?** is defined in EoPL

```
(define (occurs-bound? sym exp)
```

7. The **lexical depth** of a bound occurrence of a variable is the number of levels of nested **lambdas** and **lets** between this occurrence and the variable's definition. In `(lambda (x) (lambda (y) (x y)))`, the occurrence of `y` has depth 0 and the occurrence of `x` has depth 1.
8. The **lexical address** of a bound occurrence of a variable is a pair `(d p)`, where `d` is that occurrence's lexical depth, and `p` is the variable's position within its "declaration list". The lexical address of a free variable includes the variable's name and an indication that it is free.

9. Example:

```
In (lambda (x z)
    (lambda (y)
      ((x y) z)))
```

The occurrence of `x` has depth 1 and position 0.

The occurrence of `y` has depth 0 and position 0.

The occurrence of `z` has depth 1 and position 1.

10. Example of output from the lexical-address procedure that you will write:

```
(lexical-address '(lambda (a b c)
                   (if (eq? b c)
                       ((lambda (c)
                          (cons a c))
                         a)
                       b)))
→
(lambda (a b c)
  (if ((: free eq?) (: 0 1) (: 0 2))
      ((lambda (c)
         ((: free cons) (: 1 0 (: 0 0)))
         (: 0 0))
       (: 0 1)))
```

11. **Exercise:** What is the output from:

Note: We are only looking at syntactic properties now.

Don't worry about whether this code has a useful meaning in Scheme.

```
(lexical-address
 '((lambda (x y)
     ((lambda (z)
        (lambda (w y)
          (+ x z w y)))
      (list w x y z))
    (+ x y z)))
 (y z)))
```
