IMPORTANT NOTICE

Texas Instruments (TI) reserves the right to make changes to its products or to discontinue any semiconductor product or service without notice, and advises its customers to obtain the latest version of relevant information to verify, before placing orders, that the information being relied on is current.

TI warrants performance of its semiconductor products and related software to the specifications applicable at the time of sale in accordance with TI’s standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Certain applications using semiconductor products may involve potential risks of death, personal injury, or severe property or environmental damage ("Critical Applications").

TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, INTENDED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT APPLICATIONS, DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS.

Inclusion of TI products in such applications is understood to be fully at the risk of the customer. Use of TI products in such applications requires the written approval of an appropriate TI officer. Questions concerning potential risk applications should be directed to TI through a local SC sales office.

In order to minimize risks associated with the customer’s applications, adequate design and operating safeguards should be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance, customer product design, software performance, or infringement of patents or services described herein. Nor does TI warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used.

About This Manual

This manual provides technical reference information for the TMS320C62x (‘C62x) multichannel evaluation module (McEVM). It includes support software documentation, application programming interface (API) references, and hardware descriptions for the ‘C62x McEVM.

The ‘C62x McEVM is a peripheral component interconnect (PCI) plug-in card that is compliant with the PCI Local Bus Specification Revision 2.1. The ‘C62x McEVM helps you evaluate characteristics of the ‘C62x digital signal processor (DSP) to determine if it meets your application requirements. It is a high-performance platform targeted for multichannel telecom and datacom applications. The ‘C62x McEVM is intended for use in a PCI expansion slot inside the PC. It can also be operated outside the PC on a desktop or lab bench with the use of an external power supply and emulator (XDS510 or XDS510WS). The power supply and emulator are not included in the kit.

‘C62x McEVM support software and APIs enable you to use the board to create applications for the ‘C62x. Software utilities are provided with the ‘C62x McEVM for board diagnostics, board configuration, and common object file format (COFF) DSP application loading. McEVM schematics and logic equations are included in this manual to ease your hardware development efforts and reduce time to market.

This manual assumes that you are familiar with working in a Windows 95, Windows 98, or a Windows NT environment and understand general and technical PC terminology. This manual specifically addresses the ‘C62x McEVM and its support software. Detailed information about the ‘C62x DSP and TI code development support tools is provided separately (see the Related Documentation From Texas Instruments section in this Preface for a list of documents and ordering information). For up-to-date information on the ‘C62x McEVM, as well as related products, visit the ‘C6000 website at http://www.ti.com/sc/c6000/.

iii
How to Use This Manual

This reference guide provides the following types of information about the 'C62x McEVM:

- Chapter 1 describes the theory of operation for the 'C62x EVM hardware, including key component identification, detailed information about each functional area, and interface descriptions.
- Chapter 2 describes the host support software utilities. It includes a complete API reference that allows you to write your own applications for the 'C62x McEVM and also includes example applications that use the API calls.
- Chapter 3 describes the DSP support software. It includes an overview of all the DSP support software components and a complete API reference that allows you to write your own DSP applications for the 'C62x McEVM. Examples applications that use the API calls are also provided.

Reference material, consisting of Appendixes A through E, provides quick reference information for the 'C62x McEVM:

- Appendix A provides the McEVM connector pinouts.
- Appendix B contains the McEVM schematics.
- Appendix C provides the McEVM complex programmable logic device (CPLD) equations.
- Appendix D summarizes the McEVM PCI configuration EEPROM.
- Appendix E provides a glossary of terms used in this manual.

Notational Conventions

This document uses the following conventions:

- Program listings, program examples, and interactive displays are shown in a special typeface. Some examples use a bold version for emphasis; interactive displays use a bold version to distinguish commands that you enter from items that the system displays (such as prompts, command output, error messages, etc.).
Here is a sample program listing with the `evm6x_close()` function highlighted for emphasis:

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE   h_board;
    h_board = evm6x_open( 0, FALSE );
      if ( h_board == INVALID_HANDLE_VALUE )
        { exit(-1);
      }
.
    .
    .
    .
    .
    evm6x_close( h_board );
```

- In syntax descriptions, the instruction or command is in **bold face**, and parameters are in *italics*. Portions of a syntax that are in **bold** should be entered as shown; portions of a syntax that are in *italics* describe the type of information that should be entered. Here is an example of a command syntax:

  ```
ev6xldr  filename
  ```

- Square brackets ([ and ]) identify an optional parameter. If you use an optional parameter, you specify the information within the brackets; you do not enter the brackets themselves. Here is an example of a command that has optional parameters.

  ```
ev6xtst  [options] [log_filename]
  ```

  `evm6xtst` is the command. This command has two optional parameters, indicated by *options* and *log_filename*.

- Device pins often are represented in groups. Device pin group notation consists of the pin name followed by brackets containing the range of pins included in the group. A colon separates the numbers in the range. For example, GD[31:0] represents the global data bus pins on a device.
The TMS320C62x family of devices is referred to as the ‘C62x. The following abbreviations are used in this manual for TI devices on the ‘C62x McEVM:

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Device Definition</th>

Information About Cautions andWarnings

This book contains cautions and warnings.

This is an example of a caution statement.
A caution statement describes a situation that could potentially damage your software or equipment.

This is an example of a warning statement.
A warning statement describes a situation that could potentially cause harm to you.

The information in a caution or a warning is provided for your protection. Please read each caution and warning carefully.
The following books describe the 'C62x processor and related support tools.

To obtain a copy of any of these TI documents, call the Texas Instruments Literature Response Center at (800)477-8924. When ordering, please identify the book by its title and literature number.

**TMS320C6000 Assembly Language Tools User’s Guide** (literature number SPRU186) describes the assembly language tools (assembler, linker, and other tools used to develop assembly language code), assembler directives, macros, common object file format, and symbolic debugging directives for the 'C6000 generation of devices.

**TMS320C6x C Source Debugger User’s Guide** (literature number SPRU188) tells you how to invoke the 'C6x simulator and emulator versions of the C source debugger interface. This book discusses various aspects of the debugger, including command entry, code execution, data management, breakpoints, profiling, and analysis.

**TMS320C6000 Optimizing C Compiler User’s Guide** (literature number SPRU187) describes the 'C6000 C compiler and the assembly optimizer. This C compiler accepts ANSI standard C source code and produces assembly language source code for the 'C6000 generation of devices. The assembly optimizer helps you optimize your assembly code.

**TMS320C6000 CPU and Instruction Set Reference Guide** (literature number SPRU189) describes the 'C6000 CPU architecture, instruction set, pipeline, and interrupts for these digital signal processors.

**TMS320C6201/C6701 Peripherals Reference Guide** (literature number SPRU190) describes common peripherals available on the TMS320C6201/C6701 digital signal processors. This book includes information on the internal data and program memories, the external memory interface (EMIF), the host port, multichannel buffered serial ports, direct memory access (DMA), clocking and phase-locked loop (PLL), and the power-down modes.

**TMS320C6000 Programmer’s Guide** (literature number SPRU198) describes ways to optimize C and assembly code for the TMS320C6000 DSPs and includes application program examples.

**TMS320C6000 Technical Brief** (literature number SPRU197) gives an introduction to the 'C6000 platform of digital signal processors, development tools, and third-party support.

**XDS51x Emulator Installation Guide** (literature number SPNU070) describes the installation of the XDS510™, XDS510PP™, and XDS510WS™ emulator controllers. The installation of the XDS511™ emulator is also described.
**TMS320 DSP Development Support Reference Guide** (literature number SPRU011) describes the TMS320 family of digital signal processors and the tools that support these devices. Included are code-generation tools (compilers, assemblers, linkers, etc.) and system integration and debug tools (simulators, emulators, evaluation modules, etc.). Also covered are available documentation, seminars, the university program, and factory repair and exchange.

**TMS320C6x Peripheral Support Library Programmer’s Reference** (literature number SPRU273) describes the contents of the ’C6x peripheral support library of functions and macros. It lists functions and macros both by header file and alphabetically, provides a complete description of each, and gives code examples to show how they are used.

**TMS320C62x Multichannel Evaluation Module User’s Guide** (literature number SPRU285) is a high-performance, multichannel telephony platform for the development, analysis, and testing of ’C62x digital signal processor (DSP) algorithms and applications. The ’C62x McEVM allows you to evaluate the ’C62x DSP and algorithms to determine if they meet your application requirements.

**TMS320C6201, TMS320C6201B Digital Signal Processors Data Sheet** (literature number SPRS051) describes the features of the TMS320C6201 and TMS320C6201B fixed-point DSPs and provides pinouts, electrical specifications, and timings for the devices.

**Related Documentation**

For up-to-date information on the ’C62x McEVM, as well as related products, visit the ‘C6000 website at:

http://www.ti.com/sc/docs/dsp/tools/c6000/index.htm

You can use the following specification to supplement this reference guide:

**PCI Local Bus Specification Revision 2.1**, PCI Special Interest Group, June 1, 1995.

Obtaining Technical Support

Before contacting Texas Instruments Technical Support, please have the following information available:

- Assembly number of your ’C62x McEVM (D600860-0001) located on the bottom side of the board
- Revision number of your ’C62x McEVM located in parentheses next to the assembly number on the bottom side of the board
- Serial number located on the bottom side of the board
- Record of the ’C62x McEVM confidence test utility results that identifies potential problems and other revision numbers (software, EEPROM, CPLD). TMS320C62x McEVM User’s Guide, Chapter 3, Running the Board Confidence Test, explains how to run the test.

- Computer’s PCI BIOS brand name and version number
Obtaining Technical Support

- Amount of memory in your computer system
- Version of the software and operating environment you are using such as Windows NT 4.0
- Version of the code generation tools you are using
- Version of the debugger you are using
- If you are using Windows 95, print out a report of your system configuration by performing the following steps:
  1) Right click on the My Computer icon on the desktop.
  2) Select the Properties menu item.
  3) Select the Device Manager tag.
  4) Select the Print button.
  5) Select the System summary radio button.
  6) Click on the OK button to print a system resource summary.
- If you are using Windows NT, perform the following steps to get system information:
  1) Select the Run... menu item from the Windows NT Start menu.
  2) Type `winmsd` at the Open prompt, and press Enter.
  3) Select the Resources tab of the Windows NT Diagnostics window.
  4) Click on the Print button to get a report.
  5) Click on OK at the Create Report window.
Have this system resource summary available when you contact technical support.

**Note:**

Check the system resource summary to see if the IRQ assigned to TI TMS320C62x McEVM is shared with another device. If it is, this is probably the problem.

Once you have this information ready, contact Texas Instruments Technical Support as specified in the *If You Need Assistance* section that follows.

Chapter 1

TMS320C62x McEVM Hardware

This chapter describes the TMS320C62x McEVM hardware, its key components and how they operate, and its various interfaces. Detailed programmer interface information such as memory maps, register definitions, interrupt usage, and required software initialization tasks are also provided.

The hardware can be divided into 14 functional areas. Each of these areas is discussed in detail in this chapter.

1.1 TMS320C62x McEVM Hardware Detailed Block Diagram

Figure 1–1 provides a detailed block diagram of the 'C62x McEVM hardware. It identifies the key components described in this chapter and shows how they interface to each other.
Figure 1–1. TMS320C62x McEVM Detailed Block Diagram
1.2 TMS320C6201 DSP

The TMS320C6201 DSP is the brain of the 'C62x McEVM. The 'C6201 DSP has the following key features:

- **VelociTI™ advanced very long instruction word (VLIW) architecture**
  - Load/store architecture
  - Instruction packing for reduced code size
  - 100% conditional instructions for faster execution
  - Intuitive, reduced instruction set computing with RISC-like instruction set

- **CPU**
  - Eight independent functional units (including two 16-bit multipliers with 32-bit results and six arithmetic logic units (ALUs) with 32/40 bit results)
  - 32 32-bit registers
  - 1600 million instructions per second (MIPS)
  - 5-ns cycle time
  - Up to eight 32-bit instructions per cycle
  - Byte-addressable with 8-, 16- and 32-bit data
  - 32-bit address range
  - Little- and big-endian support
  - Saturation
  - Normalization
  - Bit-field instructions (extract, clear, left-most bit detection)

- **Memory/peripherals**
  - Glueless external memory interface to synchronous memories such as SBSRAM and SDRAM
  - Glueless external memory interface to asynchronous memories such as SRAM and EPROM
  - 4-channel direct memory access (DMA)
  - Host port interface (HPI) with dedicated auxiliary DMA channel providing access to entire processor memory space
  - Two multichannel buffered serial ports (McBSPs) for direct interfacing to telecommunication, audio, and other serial devices
- Two general-purpose timers
- Multiply-by-4 phase locked loop (PLL) and multiply-by-1 PLL-bypass options
- 1M-bit on-chip memory (2K x 256 bits of program memory/64K bytes of data memory)

Miscellaneous
- IEEE-1149.1 (JTAG) boundary-scan compatible for emulation and test support
- 352-lead ball grid array (BGA) package
- 0.18-micron/5-level metal process with CMOS technology
- 3.3-V I/O and 1.8-V internal core voltages

Figure 1–2 shows the 'C6201 core, peripherals, and external interfaces.

Because the 'C62x McEVM is a hardware reference design intended to provide you with maximum flexibility, it supports all of the DSP's external interfaces. The 'C62x McEVM uses the PLL clock generator interface to support multiply-by-1 and multiply-by-4 clock modes with CPU clock rates of 33.25 MHz, 50 MHz, 133 MHz, and 200 MHz. The JTAG test/emulation interface supports both embedded and external emulation for source code debugging. The control interface resets the DSP, provides external interrupts, chooses data endian mode, and selects the DSP's boot method. The external memory interface (EMIF) supports synchronous SBSRAM and SDRAM memories and asynchronous accesses to the CPLD registers, Multi-Vendor Integration Protocol (MVIP) flexible MVIP interface circuit (FMIC), T1/E1 transceiver, PCI controller, and expansion memory. The EMIF is also brought out to an expansion memory interface connector for daughterboard use. The host port interface (HPI) is used for bidirectional data transfers between the PC and the DSP. The timer interfaces are provided on the expansion peripheral interface connector for daughterboard use. The multichannel buffered serial ports provide interfaces to an onboard MVIP FMIC and/or a daughterboard connected to the expansion peripheral interface.
Figure 1–2. TMS320C6201 Core, Peripherals, and External Interfaces
1.3 DSP Clocks

The 'C62x McEVM provides quad DSP clock support, which allows you to run the DSP core at these rates:

- Full speed (200 MHz)
- Speed of the SBSRAM (133 MHz)
- Multiply-by-1 clock modes (33.25 MHz and 50 MHz)

Typically, you will use either the full-speed or SBSRAM-speed DSP clock. Depending on the application, one speed may be more efficient than the other. You can perform benchmarks using both clocks to determine optimal performance for a particular application.

The McEVM uses two half-size oscillators, along with a TI SN74LVT125 quad bus buffer device, to provide 33.25- and 50-MHz CLKIN signals to the 'C6201. The use of the 'LVT125 device provides multiple functions, including 5-V to 3.3-V signal level translation, clock selection, and clock edge control with fast rise and fall times required by the DSP.

The clock selection is made via a DIP switch during external operation or via a software switch for internal PCI operation. Clock select control logic in the complex programmable logic device (CPLD) controls the 'LVT125 buffer output enable that corresponds to the selected clock oscillator. The CPLD provides break-before-make clock switching between the two clock oscillators to prevent any output contention.

The McEVM provides user options for selecting the CLKIN frequency (33.25 or 50-MHz) and the clock mode (multiply-by-1 or multiply-by-4), so the CLKOUT1 (CPU clock) frequency can be 33.25 MHz, 50 MHz, 133 MHz, or 200 MHz (see Table 1–1). The SBSRAM clock (SSCLK) can be configured by the DSP software to be one-half the CPU clock (CLKOUT1) or the same as CLKOUT1. The SDRAM clock (SDCLK) is always one-half of CLKOUT1. The CPLD also controls the DSP’s CLKMODE and PLLFREQ control inputs based on the clock mode selection.

1.4 External Memory

The 'C62x McEVM provides one bank of 128K × 32-bit words of 7.5-ns (133-MHz) SBSRAM and two banks of 4M × 32-bit words of 10-ns (100-MHz) SDRAM. An expansion memory connector is also provided to enable asynchronous memory and memory-mapped devices to be added using a daughterboard. The external SBSRAM and SDRAM devices on the board are 3.3-V devices. The expansion memory connector is able to support both 3.3-V and 5-V devices because 'ALVCH16245 5-V-tolerant buffers are used.

The EMIF address and data busses are connected to the high-speed SBSRAM and SDRAM memories using series termination. Buffers and transceivers are used to buffer signals to other memory-mapped devices to preserve signal integrity, limit loading on the 'C6201 outputs, and provide the necessary drive to meet timing requirements. Low-voltage data transceivers that are 5-V tolerant provide voltage translation and the necessary drive to a daughterboard.

Figure 1–3 and Figure 1–4 show the topologies of the EMIF data and address busses on the McEVM, respectively.
Figure 1–3. EMIF Data Bus Topology

Legend:
- ED: DSP EMIF data
- GD: Global data bus
- XD: Expansion memory data
- AOD: PCI add-on data

Note: The transceiver signal assignments provide a functional overview only. The actual signal assignments are optimized for layout.
1.4.1 SBSRAM

The McEVM provides 128K × 32-bit words of SBSRAM. The SBSRAM used on the McEVM is directly connected to the DSP with no glue logic or buffers required, because the ’C6201 EMIF provides a direct interface to industry-standard SBSRAM devices. The bank of SBSRAM is mapped into the DSP’s CE0 memory space, allowing it to be used for program booting, assuming that it has been initialized by host software or the emulator. It has a 7.5-ns cycle time (133 MHz) and provides 128K × 32-bit words of memory in a single 100-pin thin quad flat pack (TQFP) package.

The SBSRAM device can be clocked by the ’C6201 at the CPU clock speed when operating at 133 MHz, one-half the clock speed when operating at 200 MHz, or at either the same as or one-half the clock speed when operating in the multiply-by-1 clock mode (33.25 MHz and 50 MHz). This selection is made based on the setting of the SSCRT bit in the EMIF global control register. Additionally, various boot modes inherently select the clock speed used for the...
SBSRAM interface. You must correctly select the SBSRAM clock rate for the selected CPU clock rate.

The 'C6201 EMIF provides signals that directly correspond to the SBSRAM pins. Because the 'C6201 can generate a new address every cycle, the SBSRAM’s ADV control input, which allows the device to generate its own addresses internally, does not have to be used. This SBSRAM control input is pulled high on the McEVM.

The SBSRAM device supports a snooze power-down mode when its ZZ input signal is a logic high. The ZZ input is controlled directly by the voltage supervisor’s logic high reset output; so, when the board is held in reset, the SBSRAM is disabled and placed into a power-down mode. Data in the SBSRAM is retained during the power-down mode.

### 1.4.2 SDRAM

The McEVM provides two banks of 4M × 32-bit words of SDRAM. Each bank is comprised of two 1M × 4 banks × 16-bit devices. The 3.3-V SDRAM used on the ‘C62x McEVM requires no glue logic to interface to the DSP because the ‘C6201 EMIF generates all the required SDRAM control and refresh signal sequences. The two banks of SDRAM are mapped into the DSP’s CE2 and CE3 memory spaces. Each bank uses all of its respective memory space’s 16M-byte address space.

The SDRAM devices are always clocked at one-half the CPU clock rate. This means that when the DSP core runs at 133 MHz, the SDRAM runs at 66.5 MHz (15 ns), and when the DSP core runs at 200 MHz, the SDRAM runs at 100 MHz (10 ns). The McEVM’s SDRAM devices are rated for 100-MHz operation.

The four SDRAM devices are driven by the DSP’s SDCLK output signal that is optimally routed in an ‘H’ configuration. Data, address, and control signals to the SDRAM devices are directly connected (via series termination resistors) to the DSP using carefully designed routing. There is no margin in the DSP’s SDRAM timing for any buffering with bus operation of 100 MHz.

The SDRAM must be refreshed periodically to maintain its data. The ‘C62x McEVM uses the DSP’s SDRAM refresh capability so the RFEN bit in the DSP’s SDRAM control register must be set to 1. The refresh period can be a maximum of 15.625 μs.

The McEVM’s CPLD includes SDRAM enable bits that are controlled via the DSP memory-mapped SDCNTL register. After reset is released, these SDRAM enables, which are connected to the SDRAM clock enable (CKE) pins, default to active, enabling the SDRAMs. When the board is held in reset or DSP software explicitly clears the register control bits, the SDRAMs are disabled and placed into a power-down mode.
An additional use of the CPLD SDRAM enable bits is the ability to independently disable the CE2 and CE3 SDRAM banks to allow these memory spaces to be used for asynchronous expansion memory on a daughterboard. When an SDRAM bank is disabled, the respective memory space can be used for asynchronous expansion memory.

### 1.4.3 Expansion Memory

The McEVM provides an asynchronous expansion memory interface connector (J8) to allow you to add memory or memory-mapped devices via a daughterboard. The expansion memory interface is mapped into the lower 3M bytes of the DSP’s 4M-byte asynchronous CE1 memory space. Expansion memory in the CE1 space is addressed from 0x1000000–12FFFFF in MAP 0 and 0x1400000–16FFFFF in MAP 1 mode. The upper 1M bytes of the CE1 memory space is allocated for onboard peripherals. This division of the CE1 memory space allows both the onboard devices and the expansion memory interface to coexist without conflicts.

Because the McEVM’s MVIP FMIC, T1/E1 transceiver, PCI controller, and CPLD registers are also accessed in the DSP’s asynchronous CE1 memory space, the CPLD provides transceiver control logic that prevents the expansion memory space from conflicting with the onboard use of the CE1 space. The CPLD monitors the CE1 signal along with the upper address signals (EA[21:20]) to determine when the lower 3M-byte expansion memory space is being accessed and enables the expansion memory transceivers accordingly. CE1 decoding in the upper 1M byte is handled by the CPLD for control of onboard peripherals.

The EMIF CE2 and CE3 memory space enables are available on the expansion peripheral interface connector (J9). These two memory spaces can also be used for asynchronous memory on the daughterboard when their respective SDRAM enable bits are not asserted in the CPLD register. The SDRAM enable bits control the SDRAM clock enables, as well as enabling the expansion memory transceivers to be turned on during CE2 and CE3 memory space accesses. This capability supports applications that do not require one or both banks of SDRAM, but need to interface to faster or additional asynchronous memory on a daughterboard.
All expansion memory interface signals are buffered using TI low-voltage, 5-V tolerant buffers/transceivers to allow both 3.3- and 5-V devices to be used on the daughterboard and to isolate the daughterboard from the onboard EMIF. The three memory space enables (CE1–CE3) are buffered versions of the DSP outputs and are not generated by decode logic. This allows fast daughterboard logic to be used as required for the application without incurring additional delay. The expansion memory transceivers isolate the daughterboard and onboard data busses to prevent bus contention.

One potential use of the expansion memory interface is to provide nonvolatile memory such as ROM or Flash memory on a daughterboard that can be used for ROM boot operation. This allows the McEVM to be autobooted at power up and reset with an application stored in nonvolatile memory. The McEVM can operate in this mode inside the PC or, more typically, in an external operating environment.

1.4.4 DSP Memory Maps

Table 1–2 and Table 1–3 show the 'C62x McEVM DSP memory maps for MAP 0 and MAP 1 modes, respectively.

1.4.5 DSP EMIF Registers

The DSP EMIF registers must be initialized before the external memory on the 'C62x McEVM can be accessed by DSP or host software. The DSP EMIF registers must be initialized by the DSP software before it accesses external memory in the no-boot and ROM-boot modes. When the HPI-boot mode is selected, the host software must initialize the EMIF registers via the HPI before HPI memory accesses are performed on external memory. This section identifies the required and recommended EMIF register values for proper McEVM operation.

The EMIF global control register must be initialized to enable the various DSP output clocks and select clock polarities, the SBSRAM clock rate (one-half the CPU clock or the same as the CPU clock), and the requester arbitration mode. The CLKOUT2 signal is routed to the expansion peripheral connector for daughterboard use. The 'C62x McEVM does not use the CLKOUT1 output, so these clocks should be disabled to minimize EMI emissions. The SDCLK output is used to clock the McEVM’s four SDRAM devices. The SBSRAM clock rate (SSCLK) can be either one-half the CPU clock or the same as the CPU clock when the CPU clock rate is 33.25 MHz, 50 MHz, or 133 MHz. When the CPU clock rate is 200 MHz, only one-half the CPU clock rate is valid for SSCLK. The requester arbitration mode selection is application dependent. For a one-half-rate SSCLK operation, a value of 0x3068 is recommended. For a full-rate SSCLK operation, a value of 0x306C is recommended.

The EMIF CE space control registers for the CE0–CE3 must be initialized to select the external memory configuration of the 'C62x McEVM. The CE1 memory space control register must be configured for a strobe period of 3 CLKOUT1 cycles for proper operation. Table 1–4 summarizes the CE space allocation of the 'C62x McEVM.

Because the 'C62x McEVM includes SDRAM, the EMIF SDRAM control and timing registers must be initialized to select timing and device width, enable refresh, initialize the SDRAM devices, and control the SDRAM refresh period. The SDRAM timing selection is dependent on the CPU clock speed, so the host or DSP software must determine its clock speed to properly initialize the timing control bits. The host and DSP can each read CPLD registers to determine the CPU clock speed based on the clock selection (33.25 MHz or 50 MHz) and clock mode (multiply-by-1 or multiply-by-4). The SDRAM devices have a tRC (refresh/active-to-refresh/active) period of 84 ns, a TRP (pre-charge-to-active) period of 24 ns, and a TRCD (active-to-read/write) period of 24 ns. Based on the determined CPU clock period, the TRC, TRP, and TRCD fields of the EMIF SDRAM control register can be initialized based on the CLKOUT2 period, as summarized in Table 1–5.

The SDRAM control register’s INIT bit must be set to 1 to initialize the SDRAM in each CE space configured for SDRAM (CE2/CE3). The RFEN bit must be set to 1 to enable EMIF SDRAM refreshes. The SDWID bit must also be set to 1 to select two, 16-bit SDRAM devices per SDRAM CE space.

The SDRAM timing register, which selects the SDRAM refresh period, must be initialized for a maximum period of 15.625 μs. The refresh period is based on CLKOUT2 cycles, so the SDRAM timing register period must have maximum values as summarized in Table 1–6.

See the TMS320C6201/C6701 Peripherals Reference Guide for detailed information about the DSP’s EMIF registers.
1.5 Expansion Interfaces

The 'C62x McEVM provides two expansion connectors that allow a daughterboard to be connected to the board. Daughterboards can be used to extend the capabilities of the McEVM and to provide custom and application-specific I/O. One expansion connector provides the DSP's asynchronous EMIF, and the other provides access to the DSP's peripherals and control/status signals. Both connectors also provide power to the daughterboard.

Most of the expansion connector signals are buffered so that the daughterboard cannot directly influence the operation of the McEVM board. The use of low-voltage, 5-V tolerant interface devices allows the use of either 5- or 3.3-V devices to be used on the daughterboard.

The 'C62x McEVM’s expansion memory and peripheral interfaces are provided with two dual-row, 80-pin connectors. These surface-mount connectors are low profile and have a 0.050-inch (1.27-mm) pitch. The recommended mating connectors provide 0.465-inch board spacing, allowing ample space for daughterboard components.

The expansion memory interface connector has a reference designator of J8 on the McEVM. The expansion peripheral interface connector is J9. See Appendix A for the pinouts of the expansion connectors.

1.5.1 Expansion Memory Interface

The expansion memory interface provides the DSP's asynchronous EMIF signals to a daughterboard. External asynchronous memories and memory-mapped devices can be added to the McEVM, including nonvolatile memory that can be used to boot the McEVM upon reset.

The expansion memory interface includes:

- **20 external address signals (EA[21:2])**. All of the DSP's 20 external address signals are available on the expansion memory interface, allowing up to 4M bytes of external memory to be addressed. However, because the CE1 memory space must be shared with onboard peripherals, only the lower 3M bytes are available to a daughterboard. If CE2 or CE3 is used for external asynchronous memory instead of SDRAM, an additional 4M bytes in each memory space can be addressed.

- **32 external data signals (ED[31:0])**. All of the DSP's 32 external data signals are available on the expansion memory interface to support full 32-bit word accesses to the daughterboard.

- **CE1 memory space enable**. The DSP's CE1 memory space enable is available on the expansion memory interface to allow asynchronous accesses to daughterboard memory and memory-mapped devices.
Expansion Interfaces

- **Four byte enables (BE[3:0])**. The DSP’s four byte enables are available on the expansion memory interface to support byte (8-bit), halfword (16-bit), and word (32-bit) daughterboard memory accesses.

- **Four asynchronous control signals**. The DSP’s asynchronous control signals (ARE, AWE, AOE, and ARDY) are provided to control asynchronous memory accesses to a daughterboard.

- **Power signals**. The expansion memory interface also provides ground, 5-V, and 3.3-V power signals to the daughterboard.

1.5.2 Expansion Peripheral Interface

The expansion peripheral interface provides the DSP’s peripheral signals to a daughterboard. This peripheral expansion capability allows serial devices and communication devices to be added to the McEVM via a daughterboard.

The expansion peripheral interface includes:

- **Seven signals for each of the serial ports (McBSP0 and McBSP1)**. The DSP’s seven McBSP1 signals are available on the expansion peripheral interface. These signals are buffered by a ’CBTD3384 device to support both 5- and 3.3-V serial devices using McBSP1 on a daughterboard. The DSP’s seven McBSP0 signals are also available when the DSP software controls onboard ’CBT3257 multiplexers that connect them to the expansion connector rather than the MVIP FMIC. This architecture provides a daughterboard with access to both of the DSP’s serial ports, which is useful in many DSP applications. Because a ’CBT3257 multiplexer is used, both 5- and 3.3-V serial devices can use McBSP0 on a daughterboard.

- **Two input/output signals for each of the timers (timer 0 and timer 1)**. The expansion peripheral interface includes each of the DSP timers’ input and output signals. This allows timer signals to be sent to the daughterboard, or timer input or events to be counted to come from the daughterboard. Each timer has one input and one output signal.

- **Interrupt, interrupt acknowledge, and identification signals**. A DSP external interrupt (DB_INT) is included on the expansion peripheral interface to allow the daughterboard to interrupt the ’C6201 to notify it of data transfers and other significant events. This interrupt is pulled down on the McEVM, so the daughterboard must drive it high to interrupt the DSP. Additionally, the DSP’s interrupt acknowledge (IACK) and interrupt identification number signals (INUM[3:0]) are available to the daughterboard.

- **Four DMA completion flags**. The DMA action complete flags (DMAC[3:0]) are available to the daughterboard on the expansion periphery.
Expansion Interfaces

eral interface. These pins provide a method of feedback to external logic generating an event for each DMA channel. The DMAC pins can also be used for general-purpose output control signals controlled from the DSP's DMA channel secondary control register.

- **Four general-purpose input/output flags.** Two general-purpose control inputs and two status outputs are brought to the expansion peripheral interface to allow the DSP to control and monitor various signals on a daughterboard. The XCNTL[0:1] and XSTAT[0:1] signals can be controlled with DSP software by accessing the CPLD’s DSP memory-mapped CNTL and STAT registers, respectively.

- **Power-down signal.** The DSP’s power-down indication signal (DSP_PD) is also brought to the expansion peripheral interface so that a daughterboard can be powered down, if desired.

- **Reset signal.** The expansion peripheral interface also provides a reset signal that is active low when the board is in the reset state. This allows circuitry on the daughterboard to be set in a known state. The reset signal is asserted for a minimum of 140 ms upon power up, via a manual reset pushbutton or under software control. A memory-mapped register bit in the CPLD’s CNTL register allows DSP software to directly control this reset signal.

- **CLKOUT2 signal for the synchronization clock.** The DSP’s CLKOUT2 signal (CPU clock divide by 2) is brought out to the peripheral expansion interface for synchronization needs on daughterboards.

- **Buffered CE2 and CE3 signals for possible memory space use when the respective SRAMs are disabled.** The DSP’s CE2 and CE3 memory space decodes are buffered and brought out to the expansion peripheral interface to provide additional fast memory decodes. This can be useful on daughterboards that have multiple devices that need fast memory decodes. The CE2 and CE3 are dedicated to SDRAM use on the McEVM board, but the EMIF control registers can be initialized for asynchronous operation, which disables the respective SDRAM banks and allows expansion asynchronous memory to be used instead. The CE2 and CE3 SDRAM enable bits in the CPLD’s DSP memory-mapped registers must also be used to shut down the respective SDRAM bank and allow the CPLD logic to enable the external data transceivers for the CE2/CE3 accesses.

- **Power signals.** The expansion peripheral interface also provides ground, 12-V, –12-V, 5-V, and 3.3-V power signals to the daughterboard.
1.5.3 Daughterboard

The 'C62x McEVM supports the mating of a daughterboard that has two 80-pin 0.050-inch × 0.050-inch TFM-series connectors from Samtec. The recommended mating connector (part number TFM–140–32–S–D–LC) is a surface-mount connector that provides a 0.465-inch mated height.

The McEVM supports two sizes of daughterboards that both use the two 80-pin connectors. The small daughterboard measures approximately 3.15 inches × 3.4 inches and mounts in the center of the board over the low-profile buffers and memories. This format is intended for daughterboards that do not require an I/O connection on the mounting bracket.

The large daughterboard measures approximately 7.5 inches × 3.4 inches and mounts from the center of the board over to the mating connector end of the board. This format is intended for daughterboards that require an I/O connection on the mounting bracket or need more space than the small daughterboard provides.

A daughterboard mounts with its component side down. This ensures that the PCI height requirement is met and no components are exposed to possible damage due to board insertions and extractions.

The McEVM provides four standoff mounting holes to support daughterboard connections. Mounting holes M3 and M4 support small daughterboards, and all four mounting holes support large daughterboards. The four mounting holes are electrically connected to the digital ground plane to provide additional daughterboard grounding.

Figure 1–5 shows the small and large daughterboard envelopes, the relationship between the two expansion connectors, and the relative location of the four mounting holes on the component side of the 'C62x McEVM board.
Figure 1–5. Daughterboard Envelopes and Connections on the '62x McEVM

It is important to note that this figure is showing the top side of the McEVM, not the actual daughterboard.

Notes:
1) All dimensions are shown in millimeters. Inch dimensions are shown in parentheses.
2) Drawing shows daughterboard envelopes and connections on the component side of McEVM board.
3) Standard-size daughterboard is 80.0 mm × 86.2 mm (3.15 in. × 3.39 in.).
4) Full-size daughterboard is 191.0 mm × 86.2 mm (7.52 in. × 3.39 in.).
6) Daughterboard mating connectors are Samtec TFM–140–32–S–D–LC.
7) Mating height is 0.465 in. (11.81 mm).
8) There are four plated holes (M2–M5) on the McEVM for standoff mounting.
9) Mounting holes M2–M5 are electrically connected to digital ground.
1.6 PCI Interface

The 'C62x McEVM’s peripheral component interconnect (PCI) interface provides plug-and-play functionality along with the ability to support high-speed target (slave) and initiator (master) modes of data transfers.

The plug-and-play feature of PCI is intended to eliminate the resource conflicts associated with ISA cards that result from user configuration of addresses and interrupts. PCI devices each provide a configuration register space within the system that can be accessed by the host prior to it being mapped into the system memory or I/O space. Access to the configuration registers is the key to PCI’s plug-and-play functionality. The PC’s BIOS executes configuration cycles after reset to identify devices on the PCI bus and to determine each of their system resource requirements, such as I/O and memory space and interrupts. PCI devices are automatically configured by the PC BIOS, to prevent system resource conflicts. The McEVM’s Windows drivers obtain information from the McEVM’s PCI controller’s configuration registers to determine where the board is located and what interrupt it uses. This allows you to simply plug the board into a PCI slot without setting any jumpers or switches.

The PCI bus operates synchronously at up to 33 MHz with a multiplexed 32-bit address/data bus. The power of PCI is its support for multiple devices to master the bus and communicate in bursts at up to 132M bytes/second (33 MHz × 4 bytes/word). A burst consists of a single 32-bit address phase, followed by sequential 32-bit data words. Only one device can be mastering the bus at any one time, but for the period that it does, it can burst data at that rate if its hardware can keep up. If it is not fast enough, a ready signal is used to throttle the transfer at the rate at which it can read or write data. Because there are typically multiple devices on the PCI bus, such as the video controller, they must all timeshare the bandwidth, so the effective transfer rate for each device is typically much lower than 132M bytes/second. The key to maximizing transfer throughput on the PCI bus is to use burst transfers when possible to avoid repetitive PCI bus arbitration and the overhead associated with single-word transfers. The PCI bridge provides a hidden central arbitration mechanism where multiple bus masters can request and be granted the bus. It also controls the length of the bursts that each device can generate. PCI transfer rates are very machine-dependent because burst transfer support varies among the various bridges used in different PCs.
1.6.1 PCI Interface Implementation

The ‘C62x McEVM implements a fully-compliant PCI Revision 2.1 interface using an industry-standard application-specific integrated circuit (ASIC) (AMCC™ part number S5933). The S5933 PCI controller interfaces directly to the PCI bus connector (P1) and handles all of the PCI-side transactions, freeing the McEVM hardware from having to handle them directly. The ‘C62x McEVM’s 32-bit PCI interface operates at up to 33 MHz in a 5-V signaling environment. The McEVM cannot be used in a 3.3-V PCI slot.

The S5933 provides PCI configuration registers that are always accessible to host software—even before the board has been mapped into the system resources. Accesses to these configuration registers are made by host software by specifying the device’s bus number, device number, and function number. The PCI configuration registers are in a unique address space, so they are not directly mapped into either the host’s I/O or memory spaces. Nonvolatile, serial EEPROM memory on the ‘C62x McEVM is used to store PCI configuration information for the board including its vendor and device IDs, memory space requirements, and operational parameters. The McEVM’s vendor ID is 0x104C (Texas Instruments), and its device ID is 0x1003.

The S5933 provides a glueless interface to the serial EEPROM that can be accessed from both the host and DSP software via memory-mapped register access. The contents of the EEPROM are automatically loaded into S5933 configuration registers at power-up reset to identify the system resource requirements and operating characteristics of the McEVM. This information is used by the PC BIOS for system resource allocation.

The McEVM uses an AT24C08A 1Kx8 serial EEPROM. The S5933 only requires 64 bytes for configuration information. Another 64 bytes is reserved for future use, so there are 896 free bytes, located from offsets 0x80 to 0x3FF, that can be used to store miscellaneous information, if desired.

The S5933 provides five base address registers (BARs). Each BAR is initialized upon power up by the nonvolatile memory to the desired size of a memory-mapped region for the device. The BIOS overwrites the BAR values with the address that it allocates to each region. The ‘C62x McEVM takes advantage of all five BARs. The first BAR (BAR0) is reserved for the PCI controller’s operation registers. The other four BARs (BAR1–BAR4) are used to interface to the JTAG test bus controller (TBC), McEVM control and status registers, and the ‘C6201 HPI. Table 1–7 summarizes the ‘C62x McEVM PCI BAR definitions.

The S5933 provides three physical interfaces:
- PCI bus
- Add-on bus
- A nonvolatile memory interface

Data movement can occur between the PCI bus and the add-on bus, as well as between the add-on or PCI bus and the nonvolatile memory. Data transfers between the PCI and add-on buses can take place through mailbox registers, FIFOs, or the pass-through data path, which is a generic memory-mapped interface.

Mailbox registers are used to pass single 32-bit values between the host and DSP. Interrupts can be used to indicate when the mailbox registers are full and empty. The S5933 has eight mailboxes that are useful for passing command and status information between the host and the DSP. There are four incoming (host-to-DSP) and four outgoing (DSP-to-host) mailboxes. The host incoming and the DSP outgoing mailboxes are the same internally. The DSP incoming and the host outgoing mailboxes are the same internally. The mailbox status can be monitored from both sides in two ways. A mailbox status register available to both sides indicates the empty/full status of bytes within the mailboxes. The mailboxes can also be configured to generate interrupts to the host and DSP. One outgoing and one incoming mailbox on each side can be configured to generate interrupts.

FIFO transfers between the PCI and add-on buses can be performed under software control or directly by hardware using the device as a bus master. This means that the DSP software can access the S5933 FIFOs directly to read and write data from and to the PCI bus, or it can program its DMA controller to handle the transfers automatically in the background.

The pass-through data path is used when the McEVM is a PCI target for JTAG TBC and DSP HPI transactions.
The S5933 registers and FIFOs are memory mapped into both the host and DSP memory spaces. The host can read the S5933 configuration registers to determine where the McEVM is located in physical memory and what host interrupt has been assigned to it. The host software also configures the S5933 through the registers for master bus transfers because it knows the physical addresses of its memory buffers and other PCI devices.

The McEVM is configured for PCI-initiated bus master transfers. In this configuration, the DSP cannot access the master read/write address and transfer count registers, and the DSP cannot be interrupted when the transfer counts reach 0. The DSP can access the other S5933 registers to read/write mailboxes, determine interrupt status, and read/write the FIFOs. Because the DSP typically uses DMA to control bus master transfers, a 'C62x DMA interrupt can be used to indicate the end of a transfer.

The S5933 supports both PCI (INTA#) and add-on interface (IRQ#) interrupts. This allows the host software and DSP software to be notified upon PCI events, such as the end of bus master transfers (host only), mailbox empty/full, and bus errors. The DSP is interrupted via its EXT_INT4 interrupt when the S5933 asserts its IRQ interrupt. The device also allows the host to control the system reset (SYSRST#) signal directly from software, so a software board reset can be invoked via the PCI bus.

Figure 1–6 provides a block diagram that shows the 'C62x McEVM’s PCI interface implementation based on the S5933 PCI controller.
Figure 1–6. PCI Interface Implementation

1.6.2 PCI Controller Operation Registers

The S5933 PCI operation registers allow the host software to:

- Configure the device and monitor its status
- Read and write mailboxes
- Reset the board
- Initiate bus master transfers
- Access the FIFOs

Table 1–8 identifies the S5933 PCI operation registers, along with their BAR0 offsets and access types. All registers are 32 bits wide and are addressed on doubleword (DWORD) boundaries.

1.6.3 PCI Add-On Bus Operation Registers

The S5933 add-on bus operation registers allow the 'C6201 DSP software to:

- Read and write mailbox messages
- Read and write FIFO data
- Control interrupts
- Provide read and write access to the PCI controller’s configuration EEPROM

The PCI add-on bus operation registers are mapped into the DSP’s CE1 asynchronous memory space starting at 0x01300000 (MAP 0) or 0x01700000 (MAP 1).

Table 1–9 summarizes the S5933 PCI controller’s 64-byte bank of add-on bus operation registers. Registers in the address offset range of 0x24–0x33 are not available because they are either under direct hardware control or are inaccessible with PCI-initiated bus mastering.

The PCI add-on FIFOs can be accessed at offset 0x20 of the PCI add-on register address space (AFIFO) for general-purpose data transfers. However, the dedicated FIFO access addresses (0x01710000/0x01310000) must be used during PCI bus master transfers.

1.6.4 PCI Slave Support

The 'C62x McEVM’s PCI slave support enables the host, or other PCI device, to access its PCI controller, JTAG TBC, CPLD, and DSP HPI registers. Once the base addresses of these devices are obtained by the host driver upon initialization, their registers can be accessed like system memory. When the host accesses the McEVM’s slave devices, the S5933 PCI controller activates the pass-through bus to indicate that a data transfer is to take place. A state machine controller implemented in the McEVM’s CPLD manages the interface between the S5933 and the three targets. This state machine monitors and asserts signals that result in the transfer of data between the S5933’s pass-through data register and the target interfaces. The S5933 decouples the state machine from the PCI bus by handling all the PCI-side transactions, so it only has to manage the reading and writing of data between the S5933 and the targets via the pass-through interface.

1.6.4.1 JTAG TBC

The 'C62x McEVM’s onboard JTAG TBC enables host software to control the 'C6201 JTAG interface for testing and emulation purposes. The debugger uses this interface to control and monitor the DSP. The 'C62x McEVM debugger shipped with the McEVM kit can be used for source code debugging on the board without requiring any additional hardware, such as an XDS510.

The JTAG TBC has 24 registers that are memory mapped at DWORD offsets starting at the address defined by the S5933’s base address register 1 (BAR1). The TBC is a 16-bit device, so the upper 16 bits of data transfers are not used.

1.6.4.2 CPLD Registers

The 'C62x McEVM’s CPLD provides 11 memory-mapped board control and status registers that the host software accesses via the PCI bus. The registers are located at DWORD offsets starting at the address defined by the S5933’s BAR2. These registers allow the host software to control and monitor the 'C62x McEVM board. Host software can reset the TBC and the DSP, configure and poll interrupts, monitor several board status signals, control software switches, observe DIP switch and DSP option signals, check the revision number of the CPLD, and utilize two hardware semaphores. The CPLD registers are only eight bits wide, so the upper 24 bits of data transfers are not used.
See section 1.8.6, *PCI Memory-Mapped Board Control/Status Registers*, for details on the PCI memory-mapped CPLD registers.

Similar to the other target interfaces, the add-on bus state machine provides the control signals that enable data transfers between the PCI controller and the board control and status registers. Whenever the S5933 indicates either a PCI read or write access to the board control and status registers (BAR2), the state machine acknowledges it by asserting S5933 and register control signals required to complete the data transfer. The lower eight bits of the S5933 add-on data bus are connected to the registers. The CPLD latches the register address during the PCI address phase and the state machine asserts register clock enable and output enable signals. The register address decoding and enable signals are used to clock data into and read data from the nine registers.

No voltage translation is required because the CPLD has 5-V tolerant inputs.

### 1.6.4.3 DSP HPI Interface

The ’C62x McEVM provides DSP host port interface (HPI) access from the PCI bus, giving host software read and write access to all of the DSP’s memory space. The ’C62x McEVM supports both random and sequential accesses using the PCI controller’s BAR3 and BAR4 memory regions, respectively.

The three ’C6201 HPI registers are memory mapped on the ’C62x McEVM at DWORD offsets starting at the address defined by the S5933’s base address register 3 (BAR3). The fourth address in the BAR3 region simply aliases to the HPID register. The three registers map directly to the DSP’s HPI control (HPIC), address (HPIA), and data (HPID) registers. Table 1–10 summarizes the HPI registers mapped into BAR3.

**Table 1–10. DSP HPI Registers (BAR3)**

<table>
<thead>
<tr>
<th>Host Byte Address</th>
<th>HPI Register</th>

</tr>
<tr>
<td>BAR3 + 0x0C</td>
<td>HPID</td>
<td>HPI data register (alias)</td>
<td>Read/write</td>
</tr>
</tbody>
</table>
Before HPI data transfers are performed successfully, the HPIC register must be properly initialized. The 'C62x McEVM handles HPI data transfers with the first halfword being the least significant word for compatibility with the little-endian PCI bus. The 'C6201 HPIC register bit HWOB must, therefore, be set to 1 to select this data ordering. A value of 0x00010001 should be written to the HPIC register at BAR3 offset 0. Any subsequent writes to the HPIC register, such as controlling host and DSP interrupts, must keep bits 0 and 16 high in the HPIC to maintain the low-word/high-word transfer order.

The 'C62x McEVM CPLD accepts data transfer requests from the S5933 PCI controller and asserts the DSP’s HPI control signals required to transfer two 16-bit words. The CPLD also handles the HPI ready control signal monitoring, so software handshaking is not required.

Byte enables asserted during the host write to the HPID register are transferred to the HPI byte enables (HBE[1:0]) by the 'C62x McEVM’s CPLD. The 'C62x McEVM therefore supports byte, word, and doubleword data writes to anywhere in the DSP’s memory space. This capability is useful for modifying individual bytes and words in memory or memory-mapped registers without corrupting the other bytes in a 32-bit word. A standard 32-bit access to the HPID register results in all four bytes being modified in the DSP memory space. From a software perspective, the pointer to the HPID register is simply modified and cast accordingly to perform byte and word write operations. Assuming a doubleword pointer to the HPID register is named HPI_DATA, a write access to byte 3 (MSbyte) of a 32-bit word would be performed as follows in C:

```
(*((unsigned char)({(unsigned long)HPI_DATA}+3))) = ByteValue;
```

Host access to the HPI via the BAR3 memory region therefore allows random read and write accesses anywhere in the DSP memory space with byte, word, and doubleword support. BAR3 accesses require that the HPIA register be updated for each transfer to a different address.

The 'C62x McEVM also provides support, using the BAR4 memory region, for sequential data transfers between the host and the DSP by taking advantage of the HPI support for read and write autoincrement accesses. This capability allows blocks of data to be moved more efficiently between the host and the DSP without incurring the overhead associated with passing the memory address each time.
The HPI data registers in BAR4 are used when data is transferred between the host and DSP in autoincrement mode. This separate region eases the decoding and makes the transfers more efficient over the PCI bus with support for sequential and burst transfers. The HPI controller in the CPLD does not care about the addresses in this range, only that an access is within the address range. All accesses to BAR4 are written directly to the HPID register, assuming that the HPIA and HPIC registers have been initialized previously with autoincrement mode selected.

Sequential HPI data accesses with burst support is provided with host accesses to the memory-mapped region defined by BAR4. BAR4 provides a 64K DWORD (256K byte) memory window that host software can address as a linear array or a circular buffer. Accesses to the BAR4 memory region result in sequential data words being transferred to the HPI data register. The BAR4 offset address is ignored, since it is assumed that the HPI's address autoincrement feature has been selected. If the host cannot access memory past the 256K byte BAR4 allocation, the PCI controller ignores the request. The 'C62x McEVM’s sequential address burst support eliminates the need for the host to arbitrate for the PCI bus as often and eliminates the need to pass the board for every data transfer.

The burst transfers to the HPI cannot occur at the full 132M bytes/s PCI data rate because the 'C6201 HPI is not a 32-bit-wide, synchronous interface. The HPI presents only a 16-bit interface; hardware handshaking via its ready signal requires multiple PCI clocks per 32-bit data transfer.

Because the 'C6201 is not 5-V signal tolerant, the S5933 outputs are translated to 3.3-V-compatible signals using two TI 'CBTD3384 buffer devices.

1.6.5 PCI Master Support

The 'C62x McEVM supports bus mastering of the PCI bus, enabling the McEVM to take control of the PCI bus and transfer data between the host and McEVM memory. The S5933 PCI controller handles the bus mastering transfers on the PCI bus. Transfers can be driven directly by 'C6201 software or automatically in the background with the DMA controller. This bus mastering support allows data transfers to be under McEVM control without continuous host intervention. The host does need to get involved initially to configure the S5933’s PCI address and transfer counters and initiate the transfer, but it is not involved at all in the actual data transfers. The host initialization is required because only the host knows the address of its, and other PCI devices’, memory buffers.
The S5933 supports bus master transfers by using two on-chip FIFOs for read and write transfers between the 'C6201 and the PCI bus. Each FIFO is 32 bits wide and 8 words deep. These FIFOs are addressed asynchronously from the DSP-side because the PCI controller and the DSP operate at different rates. The S5933 provides two FIFO flags that indicate the status of each FIFO (RDEMPNT/WRFULL). These FIFO flags are used to control the flow of data to and from the DSP.

The S5933 registers and FIFOs are memory mapped into the DSP’s CE1 asynchronous memory space, along with the MVIP FMIC and T1/E1 transceiver control registers, DSP memory-mapped CPLD registers, and asynchronous expansion memory. State machines in the CPLD manage the interface between the 'C6201 and the S5933 read and write FIFOs. They monitor S5933 FIFO flags and accesses by the DSP to the S5933 FIFO at address 0x1310000 (0x1710000), and generate the external interrupts to the DSP to control the data transfers. The FIFOs must be accessed using the dedicated memory-map address, rather than the PCI add-on register offset, for the external interrupts to be generated.

Master read transfer support and master write transfer support are independently enabled by the DSP by setting two bits in the CPLD’s memory-mapped FIFOSTAT register. When the PCIMREN bit (bit 1) is set, the CPLD generates EXT_INT5 interrupts to the DSP whenever data is available to be read in the PCI controller’s read FIFO. When the PCIMWEN bit (bit 0) is set, the CPLD generates EXT_INT6 interrupts to the DSP whenever the write FIFO is not full and can accept data. Typically, the DSP triggers DMA read and write transfers on these interrupts for the most efficient transfers. However, the FIFO flags in the CPLD’s FIFOSTAT register or the interrupts themselves can also be polled to drive the data transfers. The PCIMREN and PCIMWEN bits must be disabled at the completion of a bus master transfer and reenabled before the next one begins.

Both the host and DSP software must perform certain initialization and control actions to configure the 'C62x McEVM for PCI bus master transfers. The host and DSP software actions can be performed independently and do not require any synchronization. Depending on the application, it may be necessary for the host software to notify the DSP software about the DSP memory space source/destination address and number of words to be transferred. The PCI bus mastering operation begins only when both sides have completed their actions.

The following subsections identify the actions that must be performed by the host and DSP software to perform PCI bus master transfers.
1.6.5.1 Host Software Actions

The 'C62x McEVM is factory-configured for PCI (host) initiated bus master transfers. This means that only the host software can enable, control, and monitor the S5933 PCI controller’s FIFO bus master on the PCI bus. The McEVM uses the PCI-initiated configuration because only the host software knows the physical memory addresses of its memory, as well as other PCI devices’ memory. For PCI-initiated bus mastering, the host software must complete certain actions to set up the FIFO bus mastering.

- **Define interrupt capabilities.** The host can be interrupted independently at the end of read and write transfers when the transfer counters reach 0. The S5933 INTCSR register’s bits 14 and 15 must be set accordingly.

- **Reset FIFO flags.** The FIFO state must be initialized to empty by resetting the FIFO flags. The S5933 MCSR register’s bits 25 and 26 can be set to reset these flags.

- **Define FIFO management scheme.** The FIFOs must be configured for the desired times that the S5933 should request mastering the PCI bus. For reads, the PCI bus can be requested when there are at least one or at least four vacant FIFO locations. For writes, the PCI can be requested when there are at least one or at least four filled FIFO locations. The S5933 does not have to request the bus as often when four or more data words are transferred during each bus grant period; using this FIFO management scheme improves throughput in most applications. The FIFO management scheme is selected by initializing the S5933’s MCSR register’s bits 9 and 13.

- **Define PCI-to-McEVM and McEVM-to-PCI priority.** It is recommended that write versus read priority be set equal by setting bits 8 and 12 of the S5933’s MCSR register.

- **Define transfer source/destination address.** The start of the PCI-side source address must be written to the S5933’s MRAR register for bus master reads, and the destination address must be written to the MWAR register for bus master writes. This address is the system’s physical memory address that is presented on the PCI bus. This address must be on a 32-bit word address (lower two address bits 0).

- **Define transfer byte count.** The S5933’s MWTC and MRTC registers must be initialized with the number of bytes to be transferred for bus master writes and bus master reads, respectively. The number of bytes must be a multiple of four because the 'C62x McEVM only supports 32-bit, bus master data transfers.
Enable bus mastering. After the other actions have been done, the read and write bus master operations can be independently enabled by setting bits 10 and 14 of the S5933’s MCSR register. This enables the S5933’s hardware to begin requesting the PCI bus to move data to and from its FIFOs.

Provide DSP software with data transfer information. In most applications, the host software must notify the DSP software of the data transfer information, such as the DSP memory space source or destination address and the number of 32-bit words to be transferred. This allows the DSP software to initialize its DMA controller to handle the transfers from the S5933 to its memory space properly. This data transfer information can be sent to the DSP via the HPI or, more commonly, through the mailbox.

Provide application-specific response to end-of-transfer interrupt. If interrupts were enabled, the host software must provide an interrupt service routine to handle PCI interrupts. The host software can perform an application-specific action in response to the end-of-transfer interrupt generated by the S5933. One example action is to prepare for the next data transfer.

The DSP must also perform certain actions in order for the bus mastering to begin.

1.6.5.2 DSP Software Actions

The ‘C62x McEVM’s DSP software is responsible for moving the data between its memory space and the S5933 PCI controller’s bidirectional FIFO to complete the data transfers. The DSP typically uses DMA to handle the reading and writing of the data from and to the S5933’s FIFO. Optionally, the DSP software can perform this data movement itself using an interrupt service routine or by polling the status of the interrupts or FIFO flags themselves.

The ‘C62x McEVM uses EXT_INT5 to control read bus master transfers from the S5933 read FIFO to the DSP memory space and EXT_INT6 to control write bus master transfers from the DSP memory space to the S5933 write FIFO. Logic in the CPLD, when explicitly enabled by the DSP software, monitors the FIFO flags and DSP accesses to the S5933 FIFO and controls the interrupts to the DSP.
The DSP software must perform the following actions to support PCI bus mastering:

- **Initialize 'C62x DMA control registers.** The primary DMA control register must be configured for incrementing address modification, 32-bit elements, and split-mode disabled. The transfers must be synchronized for reads or writes by initializing the RSYNC and WSYNC bits appropriately. For bus master reads, read synchronization based on EXT_INT5 must be selected. For bus master writes, write synchronization based on EXT_INT6 must be selected.

  The secondary DMA control register can be configured to interrupt the DSP upon the transfer completion.

- **Initialize 'C62x DMA source/destination address register.** The source address register must be initialized for bus master writes, and the destination address register must be initialized for bus master reads.

- **Initialize 'C62x DMA transfer counter register.** The transfer counter register’s FRAME COUNT and ELEMENT COUNT values must be set to select the number of frames and 32-bit elements that are to be transferred. This value must match the number of transfers that the host software indicates.

- **Start the 'C62x DMA controller.** The DMA controller can be started by writing 01b to the START bits of the primary DMA control register.

- **Enable CPLD master transfer support.** Before bus master transfer interrupts are generated to the DSP, the respective CPLD control bits must be set to 1 as needed. For bus master writes, the CPLD’s FIFOSTAT PCIMWEN bit must be set to 1. For bus master reads, the PCIMREN bit must be set to 1. These enables activate a state machine in the CPLD that generates the external interrupts to the DSP.

- **Provide application-specific response to end-of-transfer interrupt.** If interrupts were disabled, the DSP software must provide an interrupt service routine to handle internal DMA block transfer complete interrupts. The DSP software can perform an application-specific action in response to the interrupt generated internal to the DSP. One example action is to prepare for the next data transfer.

- **Disable CPLD master transfer support.** To disable the bus master interrupts to the DSP and put the CPLD state machine in an idle state, the PCI bus master enable bits in the CPLD’s FIFOSTAT register must be cleared to 0. The bus master enable bits must be disabled before another master transfer is started.
1.7 JTAG Emulation

The McEVM provides embedded JTAG emulation, which is accessible via the PCI bus, as well as support for an external XDS510 emulator. The selected JTAG method is user configurable via the DIP switches when the board is operated outside the PC or via the software switches when it is in the PC.

The TI SN74ACT8990 JTAG test bus controller (TBC) provides memory-mapped control of the 'C6201’s JTAG interface. This allows the 'C62x McEVM C source debugger to be used with the McEVM without an external emulator.

The 'C62x McEVM’s embedded emulation support provides several benefits:

- Emulation is supported without external cabling, monitor software, or consumption of user resources.
- Easy access to the 'C6201 supports high-level language (HLL) debuggers, factory testing, and field diagnostics.
- System boot ROMs are not needed. The host can download all necessary program and data information through the emulation port.

The TBC is presented to the PC host software as 24 memory-mapped registers. Each register is mapped at 32-bit (DWORD) address boundaries, but only the lower 16 bits of data words are connected to the 16-bit TBC device. The PCI controller’s pass-through interface is used to access the slave TBC. The CPLD includes a state machine that manages the S5933-to-TBC data transfers via the pass-through interface.

A 14-pin (two rows of seven pins) header on the McEVM (J10) supports an external XDS510 or XDS510WS emulator connection. This connection is required for debugging the McEVM outside of a PC. Two TI CBT quad 2:1 multiplexer devices (SN74CBT3257) are used to provide the 5-V to 3.3-V translation required from the TBC to the 'C6201 and the selection between internal and external JTAG emulation. The JTAG interface to the 'C6201 consists of seven signals: TMS, TDO, TDI, TCLK, TRST, EMU1, and EMU0. The two quad multiplexer devices are required to switch and translate seven signals. The use of the CBT devices also allows 3.3- or 5-V external emulator connections. Figure 1–7 shows how the DSP’s JTAG signals are selected between the TBC and the external JTAG header using the CBT multiplexers.
The TBC does not directly provide pins dedicated for the EMU0, EMU1, and TRST signals that are present on the external JTAG header. However, the TBC can control and monitor these signals using the available TMSx pins. The TMS2 and TMS3 signals monitor the EMU0 and EMU1 signals from the ‘C6201, respectively. The TMS5 signal controls the DSP’s TRST signal. The host emulation software monitors and controls these signals via the TBC’s PCI interface.

You can select between internal and external JTAG emulation via DIP switch SW2–9 during external operation or via a software switch for internal PCI operation. The selection controls the multiplexers’ select input signal accordingly.

A 10.368-MHz JTAG clock (TCK) is provided by the XDS510 or XDS510WS when external JTAG emulation is selected. The McEVM provides a 16.625-MHz clock when the JTAG TBC is used for embedded emulation. The 16.625-MHz clock is derived from the McEVM’s 33.25-MHz oscillator output using a single SN74F74 D-type flip-flop device configured for a divide-by-2 operation.
1.8 Programmable Logic

The 'C62x McEVM uses a CPLD (Altera™ part number EPM7256S) to implement the board’s required glue logic and to provide control and status interfaces for both host and DSP software. The CPLD provides the following functions:

- Reset control
- Power management
- Dual DSP clock oscillator control
- PCI controller/DSP interface control
- PCI memory-mapped board control/status registers
- DSP memory-mapped control/status registers
- PCI and DSP interrupt control
- CE1 memory decoding
- Data transceivers control
- User options control
- Dual hardware semaphores

The EPM7256S CPLD is a 208-pin plastic quad flat pack (PQFP) device that provides 5000 usable gates, 160 user I/O pins, and a 10-ns pin-to-pin delay. The device is EEPROM-based and is in-system programmable via a dedicated JTAG interface presented as a 10-pin header on the McEVM. This header is a factory option that is not installed.

The EPM7256S uses 5 V for internal operation and input buffers and 3.3 V for output drivers. This provides an optimal design with fast internal speed and the ability to interface with both 3.3- and 5-V devices on the McEVM.

Figure 1–8 provides an overview of the CPLD’s functions and their associated interfaces.

- ‘C6201 DSP
1.8.1 Reset Control

The CPLD works in tandem with a Maxim MAX708S voltage supervisor to provide several types of reset signals on the 'C62x McEVM.

The McEVM supports several methods to reset the board, DSP, JTAG TBC, and daughterboard. There are five reset sources:

- Power-up and undervoltage resets from the voltage supervisor
- Manual pushbutton reset
- PCI system reset from the PCI controller
- Daughterboard reset under DSP software control
- DSP and TBC resets under host software control

The MAX708S voltage supervisor asserts an active low reset to the CPLD whenever the 3.3-V supply is below 3.0 V, such as during power up and brown-out conditions. Additionally, the voltage supervisor supports an external reset control signal generated by the CPLD that forces a board reset whenever the reset pushbutton is pressed or a PCI system or software reset is received. The MAX708S provides an output signal that indicates when the 1.8-V or 2.5-V supply has an undervoltage condition that the CPLD uses to control the DSP reset. The DSP is held in reset whenever either its core or I/O voltage is below a defined threshold.

The S5933 PCI controller provides a SYSRST# output that causes a reset whenever the PCI bus is reset, such as when a system is rebooted with Ctrl-Alt-Del or when the host software sets a bit in its MCSR register. The SYSRST# signal provides an automatic reset signal as well as a software-controlled reset control, similar to the voltage supervisor’s support for automatic and manual reset.

The DSP software has access to a memory-mapped CPLD register bit that directly controls the reset to the daughterboard. This daughterboard reset (XRESET#) is asserted low during reset but defaults to an inactive high upon release of reset. This provides a reset to the daughterboard whenever the McEVM is in reset, but it does not hold the daughterboard in reset. Subsequent control over the daughterboard reset is exclusively under DSP software control.

Both the DSP and JTAG TBC can be individually reset under host software control. PCI memory-mapped CPLD register bits allow the host software to directly control the reset signals to both the 'C6201 DSP and JTAG TBC. This is useful when doing controlled booting such as an HPI boot, performing a simple DSP reset operation, or putting the TBC in a known state. During board reset, the DSP and JTAG TBC are also held in reset. The DSP is also forced into reset whenever the board is in reset or its core voltage is not within
The board reset is produced when either the MAX708S indicates a reset (power up, undervoltage condition, or manual switch reset) or the PCI controller indicates a reset (PCI reset or manual software reset). The MAX708S provides two board reset signals: one active low and the other active high. The active-low board reset is routed to the CPLD, which directly controls the reset to the DSP, JTAG TBC, and daughterboard. The active-high board reset from the MAX708 is routed directly to the SBSRAM snooze (ZZ) input to put the device in an inactive, low-power state. When the McEVM board is held in reset, it cannot respond to host PCI accesses.

The PCI bus can only reset the PCI controller at power up and whenever the system is reset. The BIOS only assigns the memory region addresses and the host interrupt upon reset of the host PC.

In the PCI environment, the McEVM software drivers can put several board devices in a low-power state by holding the board in reset. The PCI specification recommends that PCI boards that dissipate more than 10 watts implement a default power reduction mode. This can be supported under driver control.

Figure 1–9 summarizes the ’C62x McEVM’s reset configuration.
1.8.2 Power Management

The *PCI Local Bus Specification Revision 2.1* recommends that PCI boards that can dissipate more than 10 watts under full operation have a power-saving state. The 'C62x McEVM CPLD includes logic that provides a power management capability that does not require additional devices. Various devices on the McEVM can be placed in a low-power state to reduce power consumption.

The McEVM’s power management feature is activated when the board is held in reset by the host software. This is achieved when the host software asserts the PCI controller’s SYSRST# signal (setting bit 24 of the S5933 PCI controller’s MCSR register).
When the McEVM board is held in reset, CPLD logic directly controls devices to power them down or put them into a low-power state. The 'C6201 DSP is held in reset, which forces it to power down. The SBSRAM is powered down by asserting its ZZ sleep input signal. The SBSRAM is disabled and put into a low-power mode by deasserting its CKE clock enable input signal. Both an external reset and the DSP’s power-down indication are provided to the expansion peripheral interface to enable power-down support on a daughterboard. Other devices on the board, such as the buffers, are indirectly placed into a low-power mode, since their inputs are static when the other devices are inactive. Table 1–11 lists the McEVM devices that are directly controlled by CPLD logic and the control signals that are used to implement the power management feature of each device.

1.8.3 Dual DSP Clock Oscillator Control

The 'C62x McEVM includes dual DSP clock oscillator support to enable operation at the 200-MHz core clock rate with one-half-rate SBSRAM timing or at the full 133-MHz SBSRAM clock rate. You have the flexibility to select the clock rate that provides the best performance for your application. This clock selection can be made with the McEVM DIP switches or from host software using the support software switches. For external operation, only the DIP switches are used to select the clock. For internal (PCI) operation, the DIP switches are selected for control by default unless overridden by host software using the software switches.

The user clock selection is used by CPLD logic to control two clock buffer enables. Each clock oscillator’s output is connected to an 'LVT125 buffer that has independent output enables. The two clock buffer outputs are connected together to drive the DSP’s CLkin input. To provide the 2:1 clock selection function and ensure that there is no contention between the oscillators, the CPLD logic performs a “break-before-make” function that ensures that only one clock oscillator is driving the DSP’s CLkin input. Figure 1–10 summarizes the DSP clock selection configuration.
1.8.4 PCI Controller/JTAG TBC Interface Control

The CPLD includes a PCI add-on bus state machine that monitors and controls the interfaces between the S5933 PCI controller and the PCI memory-mapped devices on the McEVM, including the JTAG TBC.

Whenever the S5933 indicates either a PCI read or write TBC access, the state machine acknowledges it by asserting S5933 and TBC control signals required to complete the data transfer. The lower 16 bits of the S5933 add-on data bus are connected to the TBC data bus interface. The CPLD latches the TBC register address during the PCI address phase, and the state machine asserts the TBC read and write strobes to enable data transfers.
1.8.5 PCI Controller/DSP Interface Control

The CPLD’s add-on bus state machine supports PCI transfers with the DSP’s HPI, as well as DSP EMIF transfers with the S5933 PCI controller. These capabilities allow the host and DSP software to communicate with one another. The host software has read/write access to the DSP’s memory space and can exchange messages with the DSP software using the S5933’s mailboxes. The DSP software has read/write access to the host PC’s memory space and can also exchange messages with the host software using S5933’s mailboxes. The S5933’s bidirectional FIFOs can also be used to pass data between the host and DSP software, although they are typically only used for bus master transfers.

The S5933’s bidirectional FIFOs can also be used to pass data between the host and DSP software, although they are typically only used for bus master transfers.

The DSP HPI can be accessed by the host software with BAR3 and BAR4 PCI accesses. Whenever the S5933 indicates either a PCI read or write HPI access, the state machine acknowledges it by asserting S5933 and HPI control signals required to complete the data transfer. The lower 16 bits of the S5933 add-on data bus are connected to the HPI data bus interface, with TI ‘CBT devices used to translate from 5- to 3.3-V signals. The internal byte-lane switching feature of the S5933 allows the low and high words of the 32-bit PCI data transfers to be output on the lower 16 bits of the add-on bus during the low and high word data transfer times to the HPI. The CPLD latches the HPI register address during the PCI address phase, and the state machine asserts the HPI control signals to enable data transfers.

CPLD output pins are shared to support both the TBC address and HPI control signals. Because an access can only be directed to one of the two at any one time, the outputs can be used for both interfaces and controlled as required for the different accesses. This is possible since the TBC address signals are don’t cares unless the TBC read/write strobes are asserted, and the HPI control signals are don’t cares unless the HPI chip and data select signals are asserted.

HPI data transfers are 16 bits wide, so a 32-bit data transfer between the host and DSP requires two HPI data transfers. The CPLD state machine manages each 16-bit data transfer by controlling the appropriate byte enable and other control signals. The state machine includes monitoring of the HPI ready output signal to determine when the next write can proceed and when read data is available.

Because the state machine is synchronous to the 33-MHz PCI clock, there is a minimum of 30 ns between control signal transitions. Therefore, the maximum transfer rate between the host and DSP is defined by the required HPI transfer protocol to transfer two 16-bit words and the 30-ns state machine clock period.
CPLD arbitration logic allows both PCI and DSP EMIF transfers to share the common PCI add-on bus. The add-on state machine controls DSP EMIF accesses to the S5933 controller’s registers and FIFOs. Because the state machine may be in the process of transferring data between the S5933 and another device when the DSP attempts to access the S5933, the state machine provides arbitration logic that holds off the EMIF access via the DSP’s ARDY input until the current add-on transfer is finished. Burst transfers are finished as soon as possible to allow EMIF accesses to have priority over the add-on bus. Logic is also included that disables the EMIF data bus connection to the add-on bus while the add-on bus is being used for other transfers to prevent data bus contention. When an EMIF access to the S5933 is taking place, PCI transfers are held until the add-on bus is released.

The CPLD add-on bus state machine controls the add-on bus control signals during EMIF accesses to the S5933 registers and FIFOs. When the EMIF is granted the add-on bus, the state machine latches the register address from the DSP’s address lines and presents them on the add-on address bus. The other add-on bus control signals are also asserted by the state machine to provide data to the DSP EMIF data bus or to latch the data into the selected S5933 register or FIFO.

There is a 32-bit data interface between the DSP EMIF and the S5933 PCI controller. The DSP’s EMIF 32-bit data bus is buffered with 'ALVCH16245 and 'CBTD3384 devices to isolate it from the PCI add-on bus and to provide voltage translation between 5 V and 3.3 V.

1.8.6 PCI Memory-Mapped Board Control/Status Registers

The CPLD’s add-on bus state machine supports PCI transfers with eleven memory-mapped board control and status registers that are also implemented in the CPLD. These registers provide the host with the following capabilities:

- Interrupt the DSP (nonmaskable interrupt)
- Enable interrupts from the DSP and TBC
- Reset the DSP and TBC
- Monitor status of McEVM devices
- Read the user-option DIP switches
- Select the user options via software switches
- Read the selected DSP options
- Read the CPLD revision number
- Utilize two hardware semaphores

Table 1–12 summarizes the PCI memory-mapped CPLD registers.

The following subsections describe each of the PCI memory-mapped CPLD registers.

**Note:**
All register bits are active high (1) for consistency and ease of use. For example, to reset the DSP, bit 0 of the CNTL register must be set to a 1. Highlighted register values denote the power-up default values.

### 1.8.6.1 PCI CNTL Register (BAR2 + 0x00)

The CNTL register enables the host software to interrupt and reset the DSP, enable interrupts from the DSP, and monitor TBC and DSP status. The host can be interrupted whenever the TBC or DSP host interrupts are asserted, or it can poll the status of these interrupt signals directly. The nonmaskable interrupt (NMI) and reset bits must be manually toggled to assert and deassert the respective signals. Table 1–13 summarizes the function of each bit in the CNTL register. Highlighted register values denote the power-up default values.

1.8.6.3 PCI SWOPT Register (BAR2 + 0x08)

The SWOPT register enables the host software to override the McEVM’s onboard user option DIP switches. This capability provides software switches, which allow the DSP options to be controlled without having to remove the PC’s cover. The values in this register are not used unless the SWSEL bit in the SWBOOT register is set to 1. Table 1–15 summarizes the function of each bit in the SWOPT register. Highlighted register values denote the power-up default values.

1.8.6.8 PCI DSPBOOT Register (BAR2 + 0x1C)

The DSPBOOT register enables the host software to read the DSP’s boot, which can either be from the DIP switches or the software switches, depending on which is selected. Table 1–20 summarizes the function of each bit in the DSPBOOT register.

Table 1–20. PCI DSPBOOT Register Bit Definitions

1.8.6.9 PCI CPLDREV Register (BAR2 + 0x20)

The CPLDREV register provides the revision of the McEVM’s CPLD. This information may be useful in assisting technical support. The revision number can be up to eight bits in length. Table 1–21 summarizes the function of each bit in the CPLDREV register.

Table 1–21. PCI CPLDREV Register Bit Definitions

1.8.6.10 PCI SEM0 Register (BAR2 + 0x24)

The SEM0 register provides a single semaphore flag that can be used to share devices or coordinate activities between the host and the DSP. Only bit 0 (PCI-SEM0) is valid in this register. A semaphore is requested by writing a ‘1’ to this bit. The bit is read back to determine if the semaphore was granted. If PCI-SEM0 is read back as ‘1’, then the host owns the semaphore. If it is read back as a ‘0’, then the host does not own the semaphore. It is important to note that a semaphore request must be explicitly made each time, since pending requests are not supported. When the host wants to relinquish the semaphore, a ‘0’ should be written to the PCI SEM0 bit. Table 1–22 summarizes the function of each bit in the semaphore 0 register.

The DSP accesses the same semaphore as the host, but only the host or the DSP can own it at any one time. At reset, the semaphore is set to ‘0’ on both sides, so neither one owns the semaphore.

Table 1–22. PCI SEM0 Register Bit Definitions

<table>
<thead>
<tr>
<th>Bit</th>

</tbody>
</table>

1.8.6.11 PCI SEM1 Register (BAR2 + 0x28)

The SEM1 register provides a single semaphore flag that can be used to share devices or coordinate activities between the host and the DSP. Only bit 0 (PCI-SEM1) is valid in this register. A semaphore is requested by writing a ‘1’ to this bit. The bit is read back to determine if the semaphore was granted. If PCI-SEM1 is read back as a ‘1’, then the host owns the semaphore. If it is read back as a ‘0’, then the host does not own the semaphore. It is important to note that a semaphore request must be explicitly made each time, since pending requests are not supported. When the host wants to relinquish the semaphore,
A ‘0’ should be written to the PCISEM1 bit. Table 1–23 summarizes the function of each bit in the semaphore 1 register.

1.8.7 DSP Memory-Mapped Control/Status Registers

The 'C62x McEVM’s CPLD provides fourteen control and status registers that are memory-mapped into the DSP’s CE1 memory space. All registers are eight bits wide and are mapped into the least-significant byte of the EMIF data bus (ED[7:0]). The registers are mapped on DWORD address boundaries for little-endian mode, but, for big-endian mode, the registers are offset by 3 to access ED[7:0]. The memory-mapped DSP registers provide the DSP software to perform the following functions:

- Control the two user-defined LEDs
- Control and monitor the daughterboard
- Control DSP NMI
- Determine the interrupt status
- Determine the operating environment
- Read the user options DIP switches
- Read the selected DSP options
- Monitor and control the PCI controller FIFO
- Control the two SDRAM banks
- Use two hardware semaphores
- Control the MVIP FMIC and local stream connections
- Reset the FMIC and FALC devices
- Support FALC and daughterboard interrupts
- Control four T1/E1 status LED indicators
- Enable and select μ-Law and A-Law handset interfaces

Address decoding generates the clock and output enable controls for the registers. Register clock enables are generated whenever the specific register is being addressed. The rising edge of the EMIF AWE output is used to clock the lower eight bits of the EMIF data bus into the registers. Data is output on the lower eight bits of the EMIF data bus when the CPLD register space is read. This register space is allocated 64K bytes in the CE1 memory space, as shown in Table 1–2 and Table 1–3. The eight registers are addressed sequentially on DWORD address boundaries.

The lower eight bits of the EMIF data bus are buffered by an 'ALVCH16245 transceiver to provide the global data bus (GD[7:0]) that is connected to the CPLD.

Table 1–24 summarizes the fourteen DSP memory-mapped control and status registers implemented in the CPLD.

</table>
The following subsections describe each of the fourteen DSP memory-mapped CPLD registers.

**Note:**

All register bits are active high (1) for consistency and ease of use. For example, to illuminate LED0, bit 0 of the CNTL register must be set to a 1. Highlighted register values denote the power-up default values.

### 1.8.7.1 DSP CNTL Register (0x01380000/0x01780000)

The CNTL register enables the DSP software to control the daughterboard, enable and select the NMI interrupt source, select the McBSP0 connection, and control the user-defined LEDs. Table 1–25 summarizes the function of each bit in the CNTL register. Highlighted register values denote the power-up default values.

1.8.7.10 DSP SEM0 Register (0x01380024/0x01780024)

The SEM0 register provides a single semaphore flag that can be used to share devices or coordinate activities between the host and the DSP. Only bit 0 (DSPSEM0) is valid in this register. A semaphore is requested by writing a ‘1’, to this bit. The bit is read back to determine if the semaphore was granted. If DSPSEM0 is read back as a ‘1’, then the DSP owns the semaphore. If it is read back as a ‘0’, then the DSP does not own the semaphore. It is important to note that a semaphore request must be explicitly made each time, since pending requests are not supported. When the host wants to relinquish the semaphore, a ‘0’ should be written to the DSPSEM0 bit. Table 1–34 summarizes the function of each bit in the SEM0 register.

The DSP accesses the same semaphore as the host, but only the host or the DSP can own it at any one time. At reset, the semaphore is set to ‘0’ on both sides, so neither one owns the semaphore.

1.8.7.11 DSP SEM1 Register (0x01380028/0x01780028)

The SEM1 register provides a single semaphore flag that can be used to share devices or coordinate activities between the host and the DSP. Only bit 0 (DSPSEM1) is valid in this register. A semaphore is requested by writing a ‘1’ to this bit. The bit is read back to determine if the semaphore was granted. If DSPSEM1 is read back a ‘a1’, then the DSP does not own the semaphore. It is important to note that a semaphore request must be explicitly made each time, since pending requests are not supported. When the host wants to relinquish the semaphore, a ‘0’ should be written to the DSPSEM1 bit. Table 1–35 summarizes the function of each bit in the semaphore 1 register.

1.8.7.12 DSP FALC Control Register (0x0138002C/0x0178002C)

The FALC control register controls the T1/E1 FALC and MVIP FMIC devices. Bits 7 through 4 of the DSP FALC control register are decoded to provide 16 timing modes (0-15) for the McEVM. Only four modes (0-3) are used for the current implementation. Modes 4-15 are equivalent to mode 0. The four modes define the states of the FALC_SYNC signal and FMIC_FRM_EN signal.
generated by the CPLD. The FALC_SYNC signal is connected to the SYNC pin of the FALC. The FMIC_FRM_EN signal controls the source of the frame signal connected to the EX_8KA pin of the FMIC. The four modes are defined in Table 1–36.

**Table 1–36. Master Timing Select Modes**

<table>
<thead>
<tr>
<th>Mode</th>
<th>FALC_SYNC State</th>

<td>Logic 0 (FMIC is timing master)</td>
</tr>
<tr>
<td>3</td>
<td>CLK2 from FMIC selected</td>
<td>Logic 0 (FMIC is timing master)</td>
</tr>
</tbody>
</table>

The FMIC provides four local serial data streams (LD-0 to LD-3). In normal operation, LD-0 is connected to the DSP, LD-1 is connected to the daughterboard, LD-2 is connected to the FALC, and LD-3 is connected to the VBAP. Bit 3 of the FALC control register permits the connections for LD-3 and LD-1 to be swapped. Bit 2 of the FALC control register permits the connections for LD-2 and LD-0 to be swapped. Bit 1 and bit 0 of the FALC control register are used to generate reset signals to the FMIC and FALC respectively. Table 1–37 summarizes the function of each bit in the FALC control register. It is important to note that 0 is the default at reset or powerup for bits 4-7.

1.8.7.13 DSP Interrupt Control Register (0x01380030/0x01780030)

The DSP interrupt control register provides access to raw and latched versions of interrupt signals generated by the McEVM daughterboard and the T1/E1 interface. Register bits 7 and 6 contain the state of the latched signals of the daughterboard and T1/E1 interface interrupts, respectively. Register bits 5 and 4 contain the state of the raw signals of the daughterboard and T1/E1 interface interrupts, respectively. Register bits 3 and 2 are not defined. Register bits 1 and 0 are used for clearing and masking the daughterboard and T1/E1 interface interrupts respectively. A ‘0’ value in a clear/mask bit enables the corresponding interrupt. A ‘1’ value in a clear/mask bit clears the corresponding interrupt. While a clear/mask bit contains a 1, the corresponding interrupt is masked. Table 1–38 summarizes the function of each bit in the interrupt control register.

1.8.8 PCI and DSP Interrupt Control

The CPLD provides interrupt control that allows the host and DSP to interrupt each other and supports various McEVM interrupts related to the daughterboard, PCI controller, T1/E1 transceiver, and JTAG TBC. The CPLD also controls DSP interrupts that are used to drive PCI bus master transfers.

The host can interrupt the DSP with three different interrupts using the following methods:

- Setting the HPI control (HPIC) register DSPINT bit (DSPINT)
- Setting the PCI memory-mapped control register DSPNMI bit (NMI)
- Accessing a PCI controller mailbox (EXT_INT4)

The HPIC register can be accessed from the host by addressing offset 0 of PCI BAR3. A host write to this address, with the DSPINT bit set to 1, causes a DSPINT interrupt to the DSP. The CPLD provides a state machine that manages the data transfers between the PCI controller and the DSP HPI.

The CPLD provides a PCI memory-mapped board control register (CNTL) that can be accessed by the host at offset 0 of PCI BAR2. When the DSPNMI bit of this register is set to 1, it causes an NMI interrupt to the DSP if the host is selected by the DSP software as the NMI interrupt source.

The host can also interrupt the DSP by writing or reading a PCI controller mailbox register mapped into PCI BAR0. The incoming and outgoing mailbox registers can generate interrupts when they become full or empty. When the selected mailbox register conditions occur, the DSP’s EXT_INT4 interrupt is asserted. The CPLD logic inverts the S5933’s IRQ# active low output signal to generate a rising-edge EXT_INT4 signal because the DSP defaults to rising-edge interrupts.

The DSP can interrupt the host by setting the HPIC register’s HINT bit to 1. This action forces the DSP’s HINT output signal to be asserted low. The CPLD includes a falling-edge detector that generates a pulse on the S5933’s external mailbox clock (EMBCLK) input, which causes an interrupt on INTA# to the host. A second falling-edge detector is used to generate an interrupt to the host when the TBC interrupt is asserted. The host software can enable HPI and TBC interrupts via the PCI memory-mapped CNTL register.

Both the host and DSP software can poll interrupt signals by reading PCI and DSP memory-mapped registers in the CPLD. The host can poll the DSP host and TBC interrupts. The DSP can poll the daughterboard, host NMI, T1/E1 transceiver, and PCI interrupts. The ability to poll interrupt signals from the software, as well as using them to interrupt execution flow, provides flexibility to the programmer that may be useful in various applications.
The CPLD includes two state machines that drive PCI bus master read and write operations based on the status of the PCI controller’s read and write FIFO flags. The PCI bus master state machines are individually enabled by the DSP software by setting bits in the DSP memory-mapped FIFOSTAT register implemented in the CPLD. When the PCIMREN bit is set, the master read state machine generates EXT_INT5 interrupts to the DSP when the PCI controller’s read FIFO flag (RDEMPERT) indicates that the read FIFO is not empty. The DSP can respond to the external interrupt with background DMA transfers or an interrupt service routine to read data from the PCI controller. The state machine waits for a DSP EMIF read of the FIFO before repeating the process. The state machine must be disabled at the end of each PCI bus master read block transfer. The CPLD provides a similar state machine for PCI bus master writes. When the PCIMWEN bit is set, the master write state machine generates EXT_INT6 interrupts to the DSP when the PCI controller’s write FIFO flag (WRFULL) indicates that the write FIFO is not full. Similar to read transfers, the DSP can use background DMA or an interrupt handler to write data to the PCI controller.

The DSP can be interrupted with four external maskable interrupts and one nonmaskable interrupt (NMI). All DSP interrupts on the ‘C62x McEVM are asserted on rising edges. Table 1–40 summarizes the DSP interrupts on the McEVM.

Table 1–40. DSP Interrupts Usage

<table>
<thead>
<tr>
<th>DSP Interrupt</th>
<th>Description of Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXT_INT4</td>
<td>PCI controller interrupts</td>

<tr>
<td>EXT_INT7</td>
<td>T1/E1 transceiver and expansion peripheral interface (XEXT_INT7)</td>
</tr>
<tr>
<td>NMI</td>
<td>Host (PCI register)</td>
</tr>
</tbody>
</table>

EXT_INT4 indicates to the DSP that a significant event has occurred as a result of activity within the PCI controller. This activity may include mailbox full/empty conditions, end of bus master transfers, a self-test request from the PCI bus, and transfer errors.

EXT_INT5 and EXT_INT6 are used to synchronize PCI bus master reads and writes, respectively. These interrupts are used to trigger the DSP's DMA controllers or a CPU interrupt service routine.
EXT_INT7 is provided to indicate an event associated with the T1/E1 transceiver has occurred. It is also shared with the expansion peripheral interface (as DB_INT) so that a daughterboard can interrupt the DSP to indicate significant events. The CPLD provides an interrupt controller that allows the daughterboard and T1/E1 transceiver to share the DSP’s EXT_INT7 interrupt.

The NMI can be asserted by the host software via a memory-mapped control register on the PCI bus.
1.8.9 CE1 Memory Decoding/Data Transceivers Control

The CPLD decodes DSP EMIF CE1 memory accesses to control various McEVM hardware and other logic within the CPLD itself.

The McEVM uses ‘ALVCH16245 data transceivers to provide data bus isolation and voltage translation. These transceivers are enabled by CPLD memory decode logic based on the CE1 memory accesses. DSP EMIF accesses to the PCI controller’s registers and FIFOs enable the PCI add-on bus transceiver. DSP EMIF accesses to the daughterboard enable the external data transceivers. DSP EMIF accesses to the MVIP FMIC, T1/E1 transceiver, handset audio codecs, CPLD registers, and daughterboard enable the global data bus transceiver. The direction of these transceivers is controlled by the DSP’s output enable (AOE) signal, which defines the direction of the data access.

A CPLD state machine, along with combinatorial logic, is used to generate the asynchronous ready (ARDY) signal to the DSP. Because the McEVM includes different types of devices in the CE1 space, there are different timing requirements for each. The CPLD generates the ARDY signal based on the type of CE1 memory access. For PCI controller accesses, the ARDY signal is not asserted until the add-on bus is available, unless the board is operated stand-alone. In stand-alone operation, the ARDY signal is always asserted for PCI controller accesses so that the EMIF does not lock up waiting for ARDY. The external ready from the daughterboard is presented to the DSP when expansion memory is accessed. The CPLD provides the ready logic that extends the asynchronous strobe time as needed for each particular access.

The CE2 and CE3 DSP memory spaces default to two banks of 4M × 32-bit SDRAM. However, if one or both of these banks of SDRAM are not required for an application, and more or faster asynchronous memory or memory-mapped devices are required, CE2 and CE3 can support expansion memory on a daughterboard. The CE3SDEN and CE2SDEN bits in the CPLD’s SDCNRL register determine whether the SDRAM banks are enabled or disabled. If a bank is disabled, it is put into a low-power mode and does not respond to accesses. Additionally, CPLD logic enables external accesses to asynchronous memory in these spaces by activating the expansion memory data transceivers.

1.8.10 User Options Control

The McEVM provides user options to select the DSP’s input clock source, endian and boot modes, and the JTAG emulation method. The CPLD includes user options control logic that selects between hardware DIP switch and software switch user options. Table 1–41 summarizes the McEVM user options.

The boot mode option selects how the DSP boots upon the release of its reset input signal. It can begin execution immediately with no boot, or it can be booted from ROM in the CE1 space or from the host port interface (HPI). The five control signals select the type of boot, the type of memory located at address 0, and the memory map (MAP 0 or MAP 1) that is to be used.

The clock mode selects whether the CPU clock (CLKOUT1) is the same as CLKin (multiply-by-1) or four times CLKin (multiply-by-4). The 'C6201 provides two pins to select the clock mode. However, both pins have the same value in each of these modes, so only one control signal needs to be used. The clock mode pins are both set to 0 for multiply-by-1 mode and 1 for multiply-by-4 mode.

The clock selection determines which of the two onboard clock sources is used. The McEVM provides both 33.25- and 50-MHz clocks. If multiply-by-4 clock mode is selected, this results in CPU clock rates of 133 MHz and 200 MHz, respectively.

The endian selection determines whether the DSP uses little- or big-endian byte/halfword addressing.

The JTAG selection determines whether the onboard JTAG controller or an external XDS510 emulator is to be used for debugging. When the 'C62x McEVM operates outside the PC in stand-alone mode, the JTAG selection is forced by the CPLD to external XDS510 use.

Three user-defined options are provided for application use. These user options can be read by both the host and the DSP software via CPLD registers.

Because the McEVM can operate in both PCI and stand-alone environments, it must support the selection of user options in both situations. When the...
McEVM is operated outside the PC, DIP switches are used to configure the board. When the McEVM is in the PC, configuration is done via software switches under software control to eliminate the need to remove the PC’s cover. This dual-use option support is transparent because it defaults to the standard DIP switch control but allows for software switch override, if desired. If software does not control the configuration from the host side, the McEVM defaults to the DIP switch settings. Therefore, in external operation, the DIP switches are used exclusively for user option selections.

Figure 1–11 shows how this dual-use option support is implemented in the McEVM’s CPLD.

The McEVM’s CPLD includes a multiplexer that selects between the hardware DIP switches and PCI-controlled software switches. Upon power up, the CPLD defaults the configuration to the DIP switch settings, providing transparent operation. Memory-mapped registers on the PCI bus allow the host McEVM driver to configure the board and DSP directly to override the hardware DIP switch settings, if desired.

Memory-mapped registers in the CPLD allow both the host and DSP software to observe DIP switches and the current DSP option selections. When the McEVM is under software switch control, the 12 DIP switches can be used by the DSP software for other purposes.

Based on the selected configuration, the CPLD provides control signals to the DSP and external hardware for clock and JTAG selection. Transparent DIP switch configuration is provided upon power up, providing power-up defaults without the need for software control.

1.9 MVIP Interface and Switch

The McEVM includes a fully compliant, enhanced MVIP-90 interface based on the Mitel MT90810 Flexible MVIP Interface Circuit (FMIC). The MVIP interface allows the McEVM to interoperate with a large base of telephone interface resources such as trunk interfaces, voice, video, fax, text-to-speech, and speech recognition boards. The MVIP interface could also be used to interconnect multiple McEVM boards via the MVIP TDM bus if desired. The TDM bus can be accessed through a connector provided at the top of the McEVM board.

In addition to meeting the requirements of the MVIP interface, the FMIC provides a switch that provides 384x384 channel non-blocking connectivity between all telephony devices on the board and the DSP via its McBSP0 serial port. This design allows the DSP to have access to every MVIP, T1/E1 and companded handset audio time slot on the board, resulting in optimal utilization of the DSP’s serial port and providing a very flexible switching arrangement. Additionally, audio monitoring and testing of various telephone channels can be accomplished by transferring samples to and from the handset interface via the FMIC.

The default MVIP configuration uses all four local streams operating with 32 timeslots at a rate of 2.048 Mbps each. For some applications, other configurations may be useful, such as when you may want to bring 64 or 128 timeslots to the DSP. The FMIC supports different local stream modes of operation which result in different local streams being active. The McEVM design provides DSP-controlled local stream switching (via the CPLD’s FALC control register) to support this type of configuration. Local stream multiplexers on the McEVM allow local streams 1 and 3, as well as 0 and 2 to be swapped in order to support higher throughput FMIC modes of operation. Figure 1–12 shows the MVIP FMIC interfaces. Note that the default local data stream assignments are shown first, with the optional swapped local data streams indicated second.
The FMIC supports eight pairs of 2.048 Mbit/sec data streams from the MVIP telephony bus, along with four local pairs of 2.048 Mbit/sec data streams. All data streams are synchronized to the same master clock and 8 kHz frame sync signals. Four local serial interfaces connect the FMIC to the following components:
MVIP Interface and Switch

- 'C6201 DSP
- VBAP handset interface
- T1/E1 transceiver
- A spare time-division multiplexed (TDM) port brought out to the expansion peripheral connector

All data streams consist of 8-bit data (typically companded with μ-law or A-law) time slots sent at an 8-kHz rate, resulting in 64-Kbps time slots.

One of the MVIP FMIC’s 2.048-Mbps local serial interfaces is connected to the 'C6201 McBSP0 interface through a pair of TI 'CBT3257 quad 2:1 multiplexers as shown in Figure 1–13. The 'CBT devices perform voltage translation between the 3.3-V DSP and the 5-V FMIC and allow the McBSP0 serial port to be connected to either the MVIP FMIC or a daughterboard at any one time, depending on your application. This allows a daughterboard to use both of the DSP’s serial ports, which is very important for many applications such as digital subscriber line technologies (xDSL). The McEVM defaults to connection to the daughterboard, and the FMIC’s initialization library function controls a memory-mapped register bit in the CPLD to connect the FMIC to the DSP’s McBSP0 interface.

The FMIC, which is mapped into the DSP’s asynchronous CE1 memory space, provides an 8-bit microprocessor interface that is compatible with the 'C6201 EMIF timing when configured for Intel non-multiplexed bus timing. The FMIC presents four read/write, 8-bit registers to the DSP which consist of master control/status, low address, address mode, and indirect data registers. The FMIC uses indirect addressing to allow the DSP to access other control registers, data memory, and connection memory. The DSP interfaces to the 5-V FMIC via TI 'ALVCH buffers and transceivers to perform voltage translation.

The DSP can configure the FMIC’s connection memory to select which time slots are routed to other time slots. For example, the DSP can configure the
FMIC to send it only T1/E1 time slots or, as another example, some MVIP time slots along with the handset audio time slots. The DSP has complete control over where all time slots are sent.

The FMIC supports all of the MVIP clocking modes, allowing the McEVM telephony data streams to be synchronized by the MVIP master clock, a local crystal, or an external 8-kHz clock that an on-chip PLL uses to generate a 4.096-MHz clock. The DSP controls which clock source is used as the master clock.

The MVIP interface consists of a 40-pin, right-angle connector at the top of the McEVM board. See Appendix A for the connector pinout.

Complete information on the MVIP FMIC device, including register definitions, is available at the following URL:

1.10 T1/E1 Interface

The McEVM provides a common T1/E1 interface that allows it to connect to T1, E1, or Integrated Service Digital Network (ISDN) primary rate trunks operating at 1.544 Mbps or 2.048 Mbps. This T1/E1 interface provides a multi-channel, digital telephone interface for the 'C6201 DSP that is ideal for processing multiple channels.

This interface is electrically compatible with T1, E1, and ISDN services provided by the phone company. It is NOT certified or approved for direct connections.

The T1/E1 interface is based on the Siemens FALC-LH (PEB2255) long-haul, fully-integrated T1/E1 framer and line interface unit (LIU). The FALC-LH is a 5-V device which combines a sophisticated framer, transmit/receive slip buffers, and a physical line interface into one device that supports both T1 and E1. This eliminates the need to have two framers and associated interfaces on the McEVM, resulting in a single framer/driver and minimal board space.

The FALC-LH provides a 2.048 Mbps serial data stream that is synchronized to the board’s master clock. This is the common rate that is used for all interfaces, therefore the FALC-LH supports this system bus clock rate even when 1.544 Mbps of T1 data is being received. The serial data stream is routed to the FMIC for switching to the desired output stream time slot, which could be the handset, the DSP or the MVIP bus.

The DSP interfaces to the FALC-LH via an 8/16-bit microprocessor interface that allows the DSP to control and receive status from the device. The FALC-LH’s interface is compatible with the ‘C6201 EMIF asynchronous timing when it is operating in the asynchronous Motorola (demultiplexed address/data) mode. The FALC-LH is mapped into the DSP’s CE1 external memory space.

The FALC-LH provides many registers and features that can be controlled by the DSP, such as alarm/error monitoring and signaling supervision. The DSP can also put the device in several different types of loopback modes (both analog and digital) for diagnostics, maintenance and troubleshooting. Other extensive test and diagnostic functions, such as PRBS test pattern generation are also available.

Another feature of FALC-LH is that it provides an interrupt output that is used by a CPLD interrupt controller to notify the DSP of significant framer events using the EXT_INT7 interrupt.
The FALC-LH's physical line interface circuit recovers clock and data from analog signals with +3 to -43 dB cable attenuation, appropriate for both short (-18 dB) and long haul T1/E1 applications. Receive line equalization is provided and programmable transmit pulse shaping, using a minimum number of external components, is provided. Data and clock jitter attenuation can be inserted on either the receive or transmit paths. A complementary driver output is provided to couple 75/100/120 ohm lines via an external transformer.

The FALC-LH analog outputs are routed to a dual-transformer for the physical interface to the T1 or E1 short-haul line.

The T1/E1 output is presented to the user as an RJ-48C twisted-pair modular jack located on the mounting bracket. The jack's wiring configuration is provided in Appendix A.

Complete information on the FALC-LH T1/E1 device, including register definitions, is available at the following URL:

http://www.siemens.de/semiconductor/products/ics/33/falc_lh.htm
1.11 Handset Interface

The McEVM includes a handset interface that allows the DSP to process voice data or route it to the TI/E1 and MVIP interfaces. Likewise, T1/E1 and MVIP data can be sent directly to the handset earphone for monitoring with or without requiring DSP intervention.

The telephone handset interface supports both A-Law and μ-Law PCM companding. Two TI voice-band audio processor (VBAP) devices, which are synchronized to the master telephony clock and framing signals, are used to provide A-Law and μ-Law PCM companding. Only one companding format is selected and used at a time. The handset interface defaults at power up to μ-Law companding as a result of the default reset value of a register bit in the CPLD.

The DSP’s software directly controls the interface with a single memory-mapped register bit in the CPLD. The value of the register bit results in two, mutually exclusive control bits that are routed to the power-down (PDN) pins of both VBAP devices. When one VBAP is enabled, the other one is in power-down mode with its output amplifier disabled and its digital output tristated. This design allows the two VBAP devices to be connected to support both companding formats, appearing just like a single dual-mode device to the DSP’s software. Figure 1–14 shows the configuration of the VBAP devices.

**Figure 1–14. McEVM VBAP Configuration**
The TI TCM320AC36 device provides the μ-Law companding, and the TCM320AC37 device provides the A-Law companding. The VBAPs are single-supply devices with glueless interfaces to an electret microphone, an earphone, and the MVIP switch. Only a few passive components (resistors and capacitors) are required for biasing, gain, and DC blocking. Because the VBAPs are interfaced to the 5-V MVIP FMIC switch and not directly to the ’C6201, no voltage translation is required, allowing a direct connection. Additionally, because one of the devices is always guaranteed to be in power-down mode by the board’s CPLD logic, forcing its output to be tristated, the two devices’ output data to the MVIP switch can be connected. This design eliminates the need for a strap or switch option and saves a local serial port on the MVIP switch that is brought out to the peripheral expansion connector, for external use. An analog multiplexer is controlled by one of the VBAP control bits to connect the microphone and earphone to the selected VBAP device.

The VBAPs can provide 13-bit linear outputs; however, for the telecom subsystem, they are configured for 8-bit companding to be directly compatible with the T1/E1 framer and MVIP data formats. The ’C6201 supports both A-Law and μ-Law PCM formats directly and converts them to linear format in hardware for processing. An added benefit of the companded data formats is that data can also be routed directly to and from the MVIP and the T1/E1 framer to support a wide variety of applications, such as monitoring channels and dropping and inserting voice and test signals.

The telephone handset interface is brought out to two 3.5mm audio jacks on the McEVM’s mounting bracket. One audio jack provides a mono microphone input and the other provides a mono earphone output. Appendix A provides the pinout of the audio jacks.
1.12 Power Supplies

The McEVM requires 1.8-V, 3.3-V, and 5-V supplies. An optional daughterboard −12-V supply is brought to the peripheral expansion interface from both the PCI bus and the external power connector. The 5-V is obtained from the PCI bus during internal operation or an external power connector during external operation. The McEVM’s PCI connector’s PRSNT1# and PRSNT2# pins are configured to indicate a maximum of 25-watts power dissipation. The 1.8-V and 3.3-V voltages for McEVM are provided by onboard switching regulators that use the PCI or external 5-V supply as its input.

1.12.1 3.3-V Voltage Regulator

The DSP’s I/O buffers, SBSRAM, SDRAM, low-voltage buffers/transceivers, and CPLD I/O buffers require 3.3 V. The 3.3-V supply is provided by an integrated switching regulator (ISR) (part number PT6405B). The PT6405B provides 3.3 V at up to 3 A. The device’s output voltage defaults to 3.3 V, but it can be adjusted in the range of 2.8 V–3.8 V by changing external resistors. The McEVM layout supports the ability to adjust the voltage with resistors, but these are not installed during manufacturing. This surface-mount device is an efficient (85%) switching regulator that is mounted flat on the board with a 0.38-inch height that is compatible with a PCI slot. This regulator is positioned on the board so that it does not interfere with the daughterboard interface.

The PT6405B only requires a couple of external capacitors, so its external interface is similar to a linear regulator because it is a module. It therefore provides the advantages of a switching regulator (efficient and runs cool) in a package that is easy to use, requiring no specialized layout or multiple devices that are required by a custom switcher design. It has already been carefully designed for minimal emissions and has been tested.

1.12.2 1.8-V Voltage Regulator

The PT6407E regulator provides the DSP’s 1.8 V core voltage with up to 3A of current. Large dynamic current requirements of the DSP are supported by the 100-μF external capacitor at the voltage regulator’s output. In addition to a carefully designed bulk and decoupling capacitor arrangement.

1.12.3 External Power Connector

The 'C62x McEVM’s external power connector is an industry-standard Molex 4-pin connector that is commonly used in PCs for disk-drive power. The external power connector is located at the bottom of the board with its pins oriented downward to prevent connection while the board is installed in the PC. When
the McEVM operates outside the PC, the power connection is easily made at
the edge of the board.

The four pins on the connector are used for 5 V, –12 V, GND, and 12 V. The
standard disk-drive power cables do not supply –12 V, so if this is required by
a daughterboard, an appropriate power supply should be used. If –12 V is not
used on the daughterboard, then a standard disk-driver power cable can be
used.

The user-supplied, external power supply should provide the following volt-
ages and currents:

- 5 V\(_{DC}\) at 4 A
- 12 V\(_{DC}\) at 500 mA
- –12 V\(_{DC}\) at 100 mA (if required by a daughterboard)

These are the voltages and their respective currents available to the ‘C62x
McEVM in a PCI slot.

Figure 1–15 shows the orientation of the external power connector pins.

Figure 1–15. External Power Connector

![Molex #15–24–4041](image)

Note: Drawing is not to scale.

---

### Preventing Power Supply Damage

To prevent power supply damage, DO NOT connect power to the
external power connector on the McEVM board when it is installed
in a PCI slot on your computer. The external power connector is on-
ly for use in standalone operation.

---

### 1.12.4 Fan Power Connector

The ‘C62x McEVM includes a connector to supply 5 V (at 100 mA) for an op-
tional fan. The heat sink/fan is not required on TMS320C6201B.
1.13 Voltage Supervision

The McEVM’s dual-voltage supervision and reset generation are provided by a single voltage supervisor device. The voltage supervisor monitors the 3.3-V and 1.8-V power supplies, provides manual reset switch debounce, and generates a clean, 140-ms minimum reset pulse.

Because the 1.8–V and 3.3-V power supplies are derived from the 5-V power supply, they reach their values after the 5 V, and their status inherently indicates the status of the 5 V. The board is held in reset until the two voltages are within specification. Whenever the 3.3-V supply is below 3 V, including during power up, the device forces a reset until the threshold is met. The voltage supervisor supports the monitoring of a secondary voltage on its power failure input. A threshold that causes reset to occur if there is a drop in the 1.8 V, is set via two external resistors configured as a voltage divider.

The device also has a manual switch reset input that allows you to manually reset the DSP. This is important, particularly for the external McEVM operation. The McEVM’s CPLD asserts this manual reset input whenever you press the manual reset pushbutton or a software reset is asserted by the PCI controller.

The voltage supervisor has two reset outputs: one is active low and the other is active high. The active low reset is used for CPLD initialization and board reset control. The active high reset is used directly to control the SBSRAM ZZ (snooze) input, which puts the SBSRAM in a power-down mode during reset. This capability is part of the power management features that are included on the ’C62x McEVM.
1.14 User Options

The 'C62x McEVM includes a 12-position DIP switch (SW2-1 through SW2-12) that allows selection of user options. The user options include the DSP’s boot and clock modes, clock oscillator selection, endian mode, JTAG selection, and three user-defined options.

1.14.1 DIP Switches

Table 1–43 summarizes the 12 switches and their functions in both the ON and OFF settings. Table 1–44 lists the valid boot mode selections for the McEVM. Highlighted table entries indicate the default switch settings. If a daughter-board that provides boot memory is used, you must select the appropriate ROM boot mode from the TMS320C6201/C6701 Peripherals Reference Guide. An ON setting translates to a logic 0, and an OFF setting translates to a logic 1.

1.14.2 Jumper Options

Two jumper options (J5 and J6) on the McEVM are related to the MVIP interface.

The MVIP 2.048 MHz (C2o) and 4.096 (C4b) clocks can be terminated using a series 1000 pF capacitor and 1 Kohm resistor. J5 is used for C2o termination and J6 is used for C4b termination. Termination is selected by connecting pins 1 and 2 on these 3-pin headers. The manufacturing default is to connect pins 2 and 3 (no termination). Termination is only required if the McEVM is on the end of the MVIP bus.

Table 1–45 summarizes the jumper options. Note that all default settings are to connect pins 2 and 3 as shown in boldface.

1.15 Indicators

The McEVM has seven LEDs that provide a power-on indication, two user-defined status indications, and four T1/E1 status indicators.

A green LED is hardwired on the 5-V supply, which can originate from the PCI bus during internal operation or the power connector during external operation. When the green LED is illuminated, it indicates that power is applied to the board.

Two red LEDs are controlled by CPLD register bits that are memory mapped in the DSP’s CE1 memory space. Both LEDs are located on top of the board. They are also under user DSP control and are application dependent.

The T1/E1 status indicators include red alarm, yellow alarm, sync, and loop indicators. A red LED is used for the red alarm indication, a yellow LED is used for the yellow alarm indication and the two green LEDs are used for the sync and loop conditions. The red alarm LED will be illuminated when a red alarm condition is declared for the received T1/E1 signal. The yellow alarm LED will be illuminated when a yellow alarm signal is received from the far-end terminal of the T1/E1 span. Because the LEDs are memory mapped in the DSP memory space, the host software can also control them from the HPI via the PCI bus. Table 1–46 provides a summary of the LED indicators.

# evm6x_abort_read

**Terminates a Pending Read Transfer**

## Syntax

```c
#include <evm6xdll.h>

BOOL evm6x_abort_read(HANDLE h_device);
```

## Description

The `evm6x_abort_read()` function terminates a pending read operation for a target board. This can be used by one thread to terminate the pending read operation of another thread.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.

## Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

## Example

In the following example, the `evm6x_abort_read()` function aborts a read operation that has not finished. The `evm6x_read` call is pending in a separate thread.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE   h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
/* Start thread to receive data */
/* Do something else, then check that receive is */
/* complete */
/* Abort read operation that is not complete */
if ( evm6x_abort_read( h_board ) )
{
    /* evm6x_abort_read() failed */
}
```
evm6x_abort_write

Terminates a Pending Write Transfer

Syntax
#include <evm6xdll.h>

BOOL evm6x_abort_write(HANDLE h_device);

Description
The evm6x_abort_write() function terminates a pending write operation for a target board. This can be used by one thread to terminate the pending write operation of another thread.

- The h_device parameter is the handle returned from a successful evm6x_open() call.

Return Value
The function returns TRUE or FALSE to indicate the success of the operation.

Example
In the following example, the evm6x_abort_write() function aborts a write operation that has not finished. The evm6x_write call is pending in a separate thread.

#include <windows.h>
#include <evm6xdll.h>

HANDLE h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* Start thread to send data */

/* Do something else, then check that transfer is */
/* complete */

/* Abort write operation that is not complete */
if ( !evm6x_abort_write( h_board ) )
{
    /* evm6x_abort_write() failed */
}
**evm6x_board_type**

**Retrieves Board Type and Version Information**

**Syntax**

```c
#include <evm6xdll.h>

BOOL evm6x_board_type(
    HANDLE h_device,
    PEVM6X_BOARD_TYPE p_board_type,
    PULONG p_rev_id);
```

**Description**

The `evm6x_board_type()` function retrieves the board type and revision ID information that is stored in the PCI configuration space of the board. The return value indicates the success of the function call.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- The `p_board_type` and the `p_rev_id` parameters are pointers to the locations in which to place the requested information. After a successful `evm6x_board_type()` function call to a McEVM board is made, the location pointed to by the `p_board_type` parameter contains the enumerated value `TYPE_MCEVM`. The location pointed to by the `p_rev_id` parameter contains the board’s revision ID as retrieved from the board’s PCI configuration space. The board revision ID is used to indicate McEVM board hardware revisions.

**Return Value**

The function returns `TRUE` or `FALSE` to indicate the success of the operation.

**Example**

In the following example, the `evm6x_board_type()` function retrieves information about the board type of the open board.

```c
#include <windows.h>
#include <stdio.h>
#include <evm6xdll.h>

HANDLE                  h_board;
EVM6XDLL_BOARD_TYPE     t_board_type;
ULONG                   ul_rev_id;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    exit(-1);
}
if ( !evm6x_board_type( h_board, &t_board_type, &ul_rev_id) )
{
    printf( "ERROR: evm6x_board_type() failed.\n" );
}
else
{
```

1-4
if ( t_board_type == TYPE_EVM )
{
    printf( "EVM Board, Revision %d\n", ul_rev_id );
} else
{
    printf( "Unknown board type.\n" );
}

---

**evm6x_clear_message_event**

_Cleans the Message Event_

### Syntax

#include <evm6xdll.h>

BOOL evm6x_clear_message_event(HANDLE h_device);

### Description

The evm6x_clear_message_event() function sets the message event to the nonsignaled state. Call this function to clear out any previous events before setting up to receive new events.

- The _h_device_ parameter is the handle returned from a successful evm6x_open() call.

### Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

### Example

In the following example, the evm6x_clear_message_event() function clears the message event for a McEVM board to the nonsignaled state.

#include <windows.h>
#include <evm6xdll.h>

HANDLE    h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

if ( !evm6x_clear_message_event( h_board ) )
{
    /* evm6x_clear_message_event failed */
    evm6x_close( h_board );
    exit(-1);
}

...
evm6x_close

Closes a Driver Connection to a Board

Syntax

```c
#include <evm6xdll.h>
BOOL evm6x_close(HANDLE h_device);
```

Description

The evm6x_close() function closes a previously opened driver connection to a board. The returned value is TRUE for a successful operation.

- The `h_device` parameter is the handle returned from a successful evm6x_open() call.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

Example

In the following example, the evm6x_close() function closes a previously opened driver connection to a McEVM board.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE   h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    exit(-1);
}

evm6x_close( h_board );
```
The evm6x_coff_display() function outputs COFF file information to stdout. This information includes details for each section, including name, size, and flags.

- The filename parameter is the filename of the COFF file to be processed.
- The clear_bss_flag parameter, if TRUE, causes the bss section to be set to 0. This is not the default behavior of the DSP debugger.
- The dump_flag parameter, if TRUE, causes all of the data being written to DSP memory to be displayed to stdout. This can be a very large amount of data.

The function returns TRUE or FALSE to indicate the success of the operation.

Example

In the following example, the evm6x_coff_display() function displays the section information of a COFF file to stdout.

```c
#include <windows.h>
#include <evm6xdll.h>

if ( !evm6x_coff_display( "example.out", FALSE, FALSE ) )
{
    /* COFF display failed */
}
```
evm6x_coff_load

Loads a COFF Image to a Board Using the HPI

Syntax

```c
#include <evm6xddll.h>
BOOL evm6x_coff_load(
    HANDLE    h_device,
    LPVOID    lp_hpi,
    char *    filename,
    BOOL      verbose_flag,
    BOOL      clear_bss_flag,
    BOOL      dump_flag);
```

Description

The `evm6x_coff_load()` function reads a COFF image and writes the data to DSP memory using the HPI. This function allows you to load data or executable images from a COFF file to DSP memory.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- The `lp_hpi` parameter is either NULL or the handle returned from a successful `evm6x_open_hpi()` call. If this parameter is NULL, the function calls `evm6x_open_hpi()` to get its own handle to the HPI then closes it before returning. If the parameter is not NULL, the function uses the provided handle to the HPI and does not close it before returning. If the HPI is currently open, it cannot be opened again because the HPI supports only one user at a time.
- The `filename` parameter is the filename of the COFF file to be processed.
- The `verbose_flag` parameter, if TRUE, causes COFF file information to be sent to stdout during COFF file processing.
- The `clear_bss_flag` parameter, if TRUE, causes the bss section to be set to 0. This is not the default behavior of the DSP debugger.
- The `dump_flag` parameter, if TRUE, causes all of the data being written to DSP memory to be displayed to stdout. This can be a very large amount of data.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.
Example

In the following example, the `evm6x_coff_load()` function loads a COFF executable to a DSP. The COFF executable is the file `example.out`, and the verbose flag is set, which causes COFF section information to be displayed to stdout during the load operation.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/*––––––––––––––––––––––––––––––––––*
reset DSP into HPI boot mode
configure emif registers
load COFF executable
unreset DSP
*––––––––––––––––––––––––––––––––––*/

    evm6x_reset_dsp( h_board, HPI_BOOT );
    evm6x_init_emif( h_board, NULL );

    if ( !evm6x_coff_load( h_board, NULL, "example.out",
                           TRUE, FALSE, FALSE ) )
    {
        /* COFF load failed */
    }

    evm6x_unreset_dsp( h_board );
```
evm6x_cpld_read_all

Reads the Contents of the CPLD Registers

Syntax

```c
#include <evm6xdll.h>

BOOL evm6x_cpld_read_all(
    HANDLE     h_device,
    PULONG     p_reg_array);
```

Description

The `evm6x_cpld_read_all()` function reads all the CPLD registers and stores the values into the ULONG array provided by the user. Note that the low byte of each ULONG is the only portion that is significant since the CPLD registers are only 8 bits wide. This function is for testing and debugging purposes. General access to the CPLD registers is not required for user programs.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- The `p_reg_array` parameter is a pointer to the array of ULONGs that will be filled with the CPLD register contents. This array must be at least 9 elements in size to hold all the CPLD registers of the EVM board.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

Example

In the following example, the `evm6x_cpld_read_all` function is used to read the current state of the CPLD registers.

```c
#include <windows.h>
#include <evm6xdll.h>
.
.
HANDLE    h_board;
ULONG     reg_array[9];

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* read the CPLD registers */
if ( !evm6x_cpld_read_all( h_board, reg_array ) )
{
    /* evm6x_cpld_read_all function failed */
}
```
# evm6x_dll_revision

## Reads EVM DLL Revision Information

### Syntax

```c
#include <evm6xdll.h>

BOOL evm6x_dll_revision(
    PULONG p_RevMajor,
    PULONG p_Rev_Minor,
    PULONG p_BuildNum)
```

### Description

The `evm6x_dll_revision()` function reads the revision information from the EVM DLL.

- The `pRevMajor` parameter is a pointer to where the major revision information of the DLL will be written.
- The `pRevMinor` parameter is a pointer to where the minor revision information of the DLL will be written.
- The `pBuildNum` parameter is a pointer to where the build number of the DLL will be written.

### Return Value

The function returns TRUE or FALSE to indicate the success of the operation.
evm6x_generate_nmi_int

Generates an NMI to a DSP

Syntax

```c
#include <evm6xdll.h>

BOOL evm6x_generate_nmi_int(HANDLE h_device);
```

Description

The `evm6x_generate_nmi_int()` function causes an NMI interrupt to be generated to the DSP. This interrupt can be disabled by the DSP.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

Example

In the following example, the `evm6x_generate_nmi_int()` function generates an NMI to the DSP on a McEVM board.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* send a NMI to the DSP */
if ( !evm6x_generate_nmi_int( h_board ) )
{
    /* evm6x_generate_nmi_int function failed */
}
```
evm6x_hpi_close  
_Closes the HPI for a Board_

Syntax

```c
#include <evm6xdll.h>
BOOL evm6x_hpi_close(LPVOID h_hpi_map);
```

Description

The `evm6x_hpi_close()` function closes an open HPI session that was started with a successful `evm6x_hpi_open()` call.

- The `h_hpi_map` parameter is the handle returned from a successful `evm6x_hpi_open()` call.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

Example

In the following example, the `evm6x_hpi_close()` function closes the HPI after reading from DSP memory.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE    h_board;
LPVOID    h_hpi;
ULONG     ul_ret_len;
ULONG     ul_buffer[2];

h_board = evm6x_open( 0, FALSE);
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* read DSP memory (2 words, 32bits each) */
ul_ret_len = 8;
ev6x_hpi_read( h_hpi, ul_buffer, &ul_ret_len, 0x1f0 );
if ( !evm6x_hpi_close( h_hpi ) )
{
    /* evm6x_hpi_close failed */
}
```
**evm6x_hpi_fill**

*Fills DSP Memory Using the HPI*

**Syntax**

```c
#include <evm6xdll.h>

BOOL evm6x_hpi_fill(
    LPVOID h_hpi_map,
    ULONG fill_value,
    PULONG p_length,
    ULONG dest_addr);
```

**Description**

The `evm6x_hpi_fill()` function fills target DSP memory space with a fixed data value. The HPI is used to access DSP memory from the host.

- The `h_hpi_map` parameter is the handle returned from a successful `evm6x_hpi_open()` call.
- The `fill_value` parameter is the 32-bit data value to be written to DSP memory space.
- The `p_length` parameter is the address of the write length. The length is updated with the actual transfer length. The length is the number of bytes to be transferred but must be a multiple of 4 because all transfers are 32-bit words.
- The `dest_addr` parameter is the fill starting address in the DSP’s memory space. The address must be 32-bit word aligned. This address is from the DSP’s point of view.

**Return Value**

The function returns TRUE or FALSE to indicate the success of the operation.

**Example**

In the following example, the `evm6x_hpi_fill()` function fills 31 words (32 bits each) of DSP memory starting with address 0x1f84 with the data pattern 0x1234cdef.

```c
#include <windows.h>
#include <evm6xdll.h>
.
HANDLE    h_board;
LPVOID    h_hpi;
ULONG     ul_ret_len;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
```
h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* fill 31 words of DSP memory (32bits each) */
ul_ret_len = 0x7c;
if ( !evm6x_hpi_fill( h_hpi, 0x1234cdef, &ul_ret_len,
                      0x1f84 ) || (ul_ret_len != 0x7c) )
{
    /* evm6x_hpi_fill() failed */
}

evm6x_hpi_close( h_hpi );
**evm6x_hpi_generate_int**

*Generates an Interrupt to a DSP Using the HPI*

**Syntax**

```c
#include <evm6xdll.h>
BOOL evm6x_hpi_generate_int(LPVOID h_hpi_map);
```

**Description**

The `evm6x_hpi_generate_int()` function causes an HPI interrupt (DSPINT) on the target DSP.

- The `h_hpi_map` parameter is the handle returned from a successful `evm6x_hpi_open()` call.

**Return Value**

The function returns TRUE or FALSE to indicate the success of the operation.

**Example**

In the following example, the `evm6x_hpi_generate_int()` function generates an interrupt to a DSP using the HPI.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE    h_board;
LPVOID    h_hpi;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* generate an HPI interrupt */
if ( !evm6x_hpi_generate_int( h_hpi ) )
{
    /* evm6x_hpi_generate_int() failed */
}
```

1-16
evm6x_hpi_open

Opens the HPI for a Board

Syntax

```c
#include <evm6xdll.h>
LPVOID evm6x_hpi_open(HANDLE h_device);
```

Description

The `evm6x_hpi_open()` function establishes a single connection per target board to the HPI of a target board. After the HPI has been successfully opened, read and write operations can be performed to DSP memory.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.

Note:

The various HPI accesses performed to a board’s HPI are protected by a MUTEX. This prevents multiple operations from interfering with each other. But, this also means that an operation may not begin immediately if another HPI operation is in progress. This could cause an HPI interrupt to the DSP to be delayed.

Return Value

The function returns one of the following values:

- Handle: Handle to be used for HPI access
- NULL: Attempt to open the HPI failed

Example

In the following example, the `evm6x_hpi_open()` function opens a handle to the HPI on a McEVM board. This handle is required for access to DSP memory through the HPI using the `evm6x_hpi_read()`, `evm6x_hpi_write()`, and `evm6x_hpi_fill()` functions.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE    h_board;
LPVOID    h_hpi;
ULONG     ul_ret_len;
ULONG     ul_buffer[2];

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
```
evm6x_hpi_read

h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* read DSP memory (2 words, 32bits each) */
ul_ret_len = 8;
if ( !evm6x_hpi_read( h_hpi, ul_buffer, &ul_ret_len, 0x1f0 ) ||
    (ul_ret_len != 8) )
{
    /* evm6x_hpi_read() failed */
}

Reads DSP Memory Using the HPI

Syntax

#include <evm6xdll.h>

BOOL evm6x_hpi_read(
    LPVOID h_hpi_map,
    PULONG p_buffer,
    PULONG p_length,
    ULONG src_addr);

Description

The evm6x_hpi_read() function transfers data from the target DSP memory space to host memory. The HPI is used to access DSP memory from the host.

- The h_hpi_map parameter is the handle returned from a successful evm6x_hpi_open() call.
- The p_buffer parameter is the address of the buffer to be filled by the read operation. This address must be 32-bit word aligned.
- The p_length parameter is the address of the read length. The length is updated with the actual transfer length. The length is the number of bytes to be transferred but must be a multiple of 4 because all transfers are 32-bit words.
- The src_addr parameter is the transfer starting address in the DSP's memory space. The address must be 32-bit word aligned. This address is from the DSP's point of view.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.
Example

In the following example, the evm6x_hpi_read() function reads two words (32 bits each) from DSP memory at address 0x1f0.

```
#include <windows.h>
#include <evm6xdll.h>

HANDLE    h_board;
LPVOID    h_hpi;
ULONG     ul_ret_len;
ULONG     ul_buffer[2];

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
    /* unable to open board */
    exit(-1);

h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);

/* read DSP memory (2 words, 32bits each) */
ul_ret_len = 8;
if ( !evm6x_hpi_read( h_hpi, ul_buffer, &ul_ret_len, 0x1f0 ) ||
    (ul_ret_len != 8) )
    /* evm6x_hpi_read() failed */

evm6x_hpi_close( h_hpi );
```
evm6x_hpi_read_single

Reads a Single Byte Using the HPI

Syntax

```
#include <evm6xdll.h>

BOOL evm6x_hpi_read_single(
    LPVOID h_hpi_map,
    LPVOID p_data, int i_size,
    ULONG src_addr)
```

Description

The evm6x_hpi_read_single function reads a single 8–bit, 16–bit or 32–bit value from the target DSP memory space. The HPI is used to access DSP memory from the host. Please note that this call reads a 32–bit aligned value from DSP memory then returns the appropriate portion of the 32–bit value based on the address and size of the request. Reads smaller than 32–bits are not supported. Thus, if a read of all the bytes of a 32–bit aligned access will produce undesirable results, then this call should not be used.

- The h_hpi_map parameter is the handle returned from a successful evm6x_hpi_open call.
- The p_data parameter is the address of the location that will be filled by the read operation. This address must be aligned for the size of the HPI access requested.
- The i_size parameter is the size of the HPI access in bytes. It can be 1 for an 8–bit access, 2 for a 16–bit access or 4 for a 32–bit access.
- The src_addr parameter is the address in the DSP’s memory space to be read. This address must be aligned to the requested access size. This address is from the DSP’s point of view.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

Example

In the following example, the evm6x_hpi_read_single function is used to read a byte (8–bits), a short (16–bits) and a long (32–bits) from DSP memory at addresses 0x800001c3, 0x800001ca and 0x800001cc.
```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE h_board;
LPVOID h_hpi;
UCHAR uc_temp;
USHORT us_temp;
ULONG ul_temp;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* read a byte from DSP memory (8-bits) */
if ( !evm6x_hpi_read_single( h_hpi, &uc_temp, 1, 0x800001c3 ) )
{
    /* evm6x_hpi_read_single() failed */
}

/* read a short from DSP memory (16-bits) */
if ( !evm6x_hpi_read_single( h_hpi, &us_temp, 2, 0x800001ca ) )
{
    /* evm6x_hpi_read_single() failed */
}

/* read a long from DSP memory (32-bits) */
if ( !evm6x_hpi_read_single( h_hpi, &ul_temp, 4, 0x800001cc ) )
{
    /* evm6x_hpi_read_single() failed */
}

evm6x_hpi_close(h_hpi);
```
evm6x_hpi_write

**evm6x_hpi_write**  
*Writes to DSP Memory Using the HPI*

**Syntax**

```c
#include <evm6xdll.h>

BOOL evm6x_hpi_write(
    LPVOID h_hpi_map,
    PULONG p_buffer,
    PULONG p_length,
    ULONG dest_addr);
```

**Description**

The `evm6x_hpi_write()` function transfers data from host memory to the target DSP memory space. The HPI is used to access DSP memory from the host.

- The `h_hpi_map` parameter is the handle returned from a successful `evm6x_hpi_open()` call.
- The `p_buffer` parameter is the address of the buffer to be transferred by the write operation. This address must be 32-bit word aligned.
- The `p_length` parameter is the address of the write length. The length is updated with the actual transfer length. The length is the number of bytes to be transferred but must be a multiple of 4 because all transfers are 32-bit words.
- The `dest_addr` parameter is the transfer starting address in the DSP's memory space. The address must be 32-bit word aligned. This address is from the DSP's point of view.

**Return Value**

The function returns TRUE or FALSE to indicate the success of the operation.

**Example**

In the following example, the `evm6x_hpi_write()` function writes two words (32 bits each) to DSP memory at address 0x1f0.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE h_board;
LPVOID h_hpi;
ULONG ul_ret_len;
ULONG ul_buffer[2];

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
/* unable to open board */
    exit(-1);
} 
```
h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}
/* write 2 words to DSP memory (32bits each) */
ul_ret_len = 8;
ul_buffer[0] = 0x12345678;
ul_buffer[1] = 0xfedcba98;
if ( !evm6x_hpi_write( h_hpi, ul_buffer, &ul_ret_len,
    0x1f0 ) ||
     (ul_ret_len != 8) )
{
    /* evm6x_hpi_write() failed */
}
evm6x_hpi_close( h_hpi );
evm6x_hpi_write_single

**evm6x_hpi_write_single**

*Writes a Single Byte, Short or Long, Using the HPI*

**Syntax**

```
#include <evm6xdll.h>

BOOL evm6x_hpi_write_single(
    LPVOID  h_hpi_map,
    ULONG   ul_data, int i_size,
    ULONG   dest_addr
);
```

**Description**

The `evm6x_hpi_write_single` function writes a single 8-bit, 16-bit or 32-bit data value to the target DSP memory space. The HPI is used to access DSP memory from the host. Please note that internal program memory does not support byte accesses. Thus, any write smaller than 32-bits to internal program memory will not modify memory as expected.

- The `h_hpi_map` parameter is the handle returned from a successful `evm6x_hpi_open` call.
- The `ul_data` parameter contains the value to be written to DSP memory.
- The low 8-bits or 16-bits of the value will be used for those size accesses.
- The `i_size` parameter is the size of the HPI access in bytes. It can be 1 for an 8-bit access, 2 for a 16-bit access or 4 for a 32-bit access.
- The `dest_addr` parameter is the address in the DSP’s memory space to be accessed. This address must be aligned to the requested access size. This address is from the DSP’s point of view.

**Return Value**

The function returns TRUE or FALSE to indicate the success of the operation.

**Example**

In the following example, the `evm6x_hpi_write_single` function is used to write a byte (8-bits), a short (16-bits) and a long (32-bits) to DSP memory at addresses 0x800001f1, 0x800001f6 and 0x800001e0.

```
Opcode
.#include <windows.h>
.#include <evm6xdll.h>
.
HANDLE    h_board;
LPVOID    h_hpi;
ULONG     ul_temp;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
```

1-24
exit(-1);
}

h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* write a byte (8–bits) to DSP memory */
ul_temp = 0x3f;
if ( !evm6x_hpi_write_single( h_hpi, ul_temp, 1, 0x800001f1 ) )
{
    /* evm6x_hpi_write_single() failed */
}

/* write a short (16–bits) to DSP memory */
ul_temp = 0xbeef;
if ( !evm6x_hpi_write_single( h_hpi, ul_temp, 2, 0x800001f6 ) )
{
    /* evm6x_hpi_write_single() failed */
}

/* write a long (32–bits) to DSP memory */
ul_temp = 0x87654321;
if ( !evm6x_hpi_write_single( h_hpi, ul_temp, 4, 0x800001e0 ) )
{
    /* evm6x_hpi_write_single() failed */
}

evm6x_hpi_close( h_hpi );
evm6x_init_emif

Initializes the EMIF Registers

Syntax

```c
#include <evm6xdll.h>

BOOL evm6x_init_emif(
    HANDLE    h_device,
    LPVOID     lp_hpi);
```

Description

The `evm6x_init_emif()` function sets the EMIF registers using HPI accesses to the DSP memory space. This operation is used in conjunction with HPI boot mode. Call the `evm6x_reset_dsp()` function to reset the DSP and put it into HPI boot mode (see page 1-35). Then, before loading code to memory, call the `evm6x_init_emif()` function to initialize the EMIF registers so that external memory on the board is accessible via the HPI.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- The `lp_hpi` parameter is the handle returned from a successful `evm6x_hpi_open()` call or NULL if the HPI is not already open. If this parameter is NULL, the HPI is opened for this operation then closed at the completion of the function. If this parameter is not NULL, the value is used as the handle for HPI accesses and is not closed at the completion of the function.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

Example

In the following example, the `evm6x_init_emif()` function properly configures the EMIF registers of the DSP for the McEVM board. This step must be done after resetting the DSP and before the DSP tries to access memory on the McEVM board.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE    h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
```
/* reset DSP into HPI boot mode */
configure emif registers
load COFF executable
unreset DSP

#include <evm6xdll.h>

BOOL evm6x_mailbox_read(
HANDLE h_device,
ULONG regNum,
PULONG p_data);

The evm6x_mailbox_read() function reads information from the EVM’s mailbox register.

- The h_device parameter is the handle returned from a successful evm6x_open() call.
- The regNum parameter represents the mailbox number to be read.
- The pData parameter is a pointer to the location in which the data will be stored.

The function returns TRUE or FALSE to indicate the success of the operation.
evm6x_mailbox_write

Writes To an EVM Mailbox

Syntax

```
#include <evm6xdll.h>

BOOL evm6x_mailbox_write(
    HANDLE h_device,
    ULONG regNum,
    ULONG data);
```

Description

The evm6x_mailbox_write() function writes information to the EVM's mailbox register.

- The h_device parameter is the handle returned from a successful evm6x_open() call.
- The regNum parameter represents the target mailbox number.
- The data parameter is the data to be written.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

---

Avoiding Simultaneous NVRAM Accesses

Make sure that NVRAM read and/or write operations do not happen at the same time from both the host and the DSP. Simultaneous accesses to NVRAM will result in invalid operations and will possibly corrupt data stored in NVRAM.

- The h_device parameter is the handle returned from a successful evm6x_open() call.
- The offset parameter is the NVRAM byte offset to be read.

---

Reads a Byte of NVRAM

Syntax

```
#include <evm6xdll.h>

BOOL evm6x_nvram_read(
    HANDLE h_device,
    USHORT offset,
    PUCHAR p_data);
```

Description

The evm6x_nvram_read() function reads a byte from a target board's NVRAM.

---

1-28
The `p_data` parameter is a pointer to the location in which to place the byte read from NVRAM.

**Return Value**
The function returns TRUE or FALSE to indicate the success of the operation.

**Example**
In the following example, the `evm6x_nvram_read()` function reads the byte value stored in NVRAM at offset 0x83.

```c
#include <windows.h>
#include <evm6xdll.h>
... 
HANDLE    h_board;
UCHAR     c_data;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
if ( !evm6x_nvram_read( h_board, 0x83, &c_data ) )
{
    /* evm6x_nvram_read failed */
} else
{
    /* byte read from offset 0x83 is in c_data */
} 
```
evm6x_nvram_write

**evm6x_nvram_write**  
*Writes a Byte to NVRAM*

**Syntax**
```c
#include <evm6xdll.h>

BOOL evm6x_nvram_write(
    HANDLE h_device,
    USHORT offset,
    UCHAR data);
```

**Description**
The `evm6x_nvram_write()` function writes a byte to a target board’s NVRAM. This write operation is not allowed to the lower 0x80 bytes of NVRAM. This space is used for PCI configuration settings and should not be modified.

**Avoiding Simultaneous NVRAM Accesses**
Make sure that NVRAM read and/or write operations do not happen at the same time from both the host and the DSP. Simultaneous accesses to NVRAM will result in invalid operations and will possibly corrupt data stored in NVRAM.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- The `offset` parameter is the NVRAM byte offset to be written.
- The `data` parameter is the byte data value to be written to NVRAM.

**Return Value**
The function returns TRUE or FALSE to indicate the success of the operation.

**Example**
In the following example, the `evm6x_nvram_write()` function writes the byte value 0x3f to NVRAM at offset 0xc3.

```c
#include <windows.h>
#include <evm6xdll.h>
...
HANDLE    h_board;
UCHAR     c_data;

h_board = evm6x_open( 0, FALSE);
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

if ( !evm6x_nvram_write( h_board, 0xc3, c_data ) )
{
    /* evm6x_nvram_write failed */
}
```
**evm6x_open**

Opens a Driver Connection to a Board

**Syntax**

```c
#include <evm6xdll.h>
HANDLE evm6x_open(
   int   board_index,
   BOOL  exclusive_flag);
```

**Description**

The `evm6x_open()` function opens a driver connection to a specific EVM or McEVM board. The returned handle is used for all further accesses to the target board.

- The `board_index` parameter is a zero-based relative index. Valid index values depend on the number of EVM and McEVM boards in a system and range from 0 to \( n - 1 \), where \( n \) is the number of boards.

- The `exclusive_flag` parameter indicates an exclusive open request of the target board. An exclusive open will fail if the target board is currently open, and additional open requests will fail for a target board that has been opened exclusively.

**Return Value**

The function returns one of the following values:

- **HANDLE** Handle to be used for all further accesses to the target board
- **INVALID_HANDLE_VALUE** Operation failed

**Example**

In the following example, the `evm6x_open()` function performs a nonexclusive open of the first EVM board in a system.

```c
#include <windows.h>
#include <evm6xdll.h>
...
int      board_index;
HANDLE   h_board;
board_index = 0; /* select the first (or only) EVM */
/* board */
h_board = evm6x_open( board_index, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
   /* board open failed */
   exit(-1);
}
...
evm6x_close( h_board );
```
evm6x_read

Reads Data from a Board

Syntax

```c
#include <evm6xdll.h>

BOOL evm6x_read(
    HANDLE h_device,
    PULONG p_buffer,
    PULONG p_length);
```

Description

The `evm6x_read()` function transfers data from the DSP to the host using the PCI bus mastering capability of the board. This transfer can take an indeterminate amount of time, depending on the DSP making data available for the transfer. To prevent the host from waiting too long for a transfer, a time-out feature is available. Use the `evm6x_set_timeout()` function to set the time-out value (see page 1-41).

Also, a transfer can be terminated at any time using the `evm6x_abort_read()` function (see page 1-2). A transfer that has been timed out or terminated still returns a success indication, but the length value returned is not the same as the originally requested transfer length.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- The `p_buffer` parameter is the address of the buffer to be filled by the read operation. This address must be 32-bit word aligned.
- The `p_length` parameter is the address of the read length. The length is updated with the actual transfer length. The length is the number of bytes to be transferred, but must be a multiple of 4 because all transfers are 32-bit words.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.
Example

In the following example, the evm6x_read() function transfers 292 bytes (73 words, 32 bits each) from the DSP into host memory using the PCI FIFO interface provided on the McEVM board. The transfer may succeed, but be incomplete if the transfer timed out or a transfer abort request was initiated from a separate thread. For additional information, see the evm6x_set_timeout() function description on page 1-41 and the evm6x_abort_read() function description on page 1-2.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE h_board;
ULONG ul_length; /* requested transfer */
    /* length in bytes */
ULONG ul_ret_len; /* returned transfer */
    /* length in bytes */
ULONG ul_buffer[1024]; /* data buffer, must */
    /* be 32bit aligned */

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

ul_length = 292;
ul_ret_len = ul_length;
if ( !evm6x_read( h_board, ul_buffer, &ul_ret_len ) )
{
    /* evm6x_read failed. */
}
else
{
    if ( ul_ret_len != ul_length )
    {
        /* evm6x_read incomplete */
        /* this can be the result of a time out or */
        /* an abort */
    }
}
```
**evm6x_reset_board**

**Resets a Board**

**Syntax**

```c
#include <evm6xdll.h>

BOOL evm6x_reset_board(HANDLE h_device);
```

**Description**

The `evm6x_reset_board()` function causes a hardware reset pulse on the target board. The target board must be opened exclusively using the `evm6x_open()` function (see page 1-31) or this function will fail. The return value indicates the success of the function call.

- The `h_device` parameter is the handle returned from a successful exclusive `evm6x_open()` call.

**Return Value**

The function returns TRUE or FALSE to indicate the success of the operation.

**Example**

In the following example, the `evm6x_reset_board()` function resets the second McEVM board in the system. This board was previously opened exclusively.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE   h_board;

/* open the second EVM board exclusively */
h_board = evm6x_open( 1, TRUE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board exclusively */
    exit(-1);
}
if ( !evm6x_reset_board( h_board ) )
{
    /* reset call failed */
} else
{
    /* reset call succeeded */
}
```
evm6x_reset_dsp

Resets a DSP

Syntax

```c
#include <evm6xdll.h>
BOOL evm6x_reset_dsp(
    HANDLE h_device,
    EVM6X_DLL_BOOT_MODE mode);
```

Description

The `evm6x_reset_dsp()` function sets the boot mode and causes a reset pulse to only the DSP. If the boot mode is set to HPI boot, the DSP is left in a halted state. To allow the DSP to begin executing, use the `evm6x_unreset_dsp()` function (see page 1-42). The return value indicates the success of the function call.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- The enumerated `mode` parameter is the boot mode in which to reset the DSP.
  - `HPI_BOOT` resets the DSP into HPI boot mode with the MAP 1 memory map.
  - `HPI_BOOT_MAP0` resets into HPI boot mode with MAP 0.
  - `NO_BOOT` selects no boot mode with MAP 1.
  - `NO_BOOT_MAP0` selects no boot mode with MAP 0.
  - The various ROMX_BOOT boot modes require that an executable boot image is present on a daughterboard.

The usual procedure for loading and starting a DSP is:

1) Reset the DSP in HPI boot mode using the `evm6x_reset_dsp()` function.

2) Configure the DSP memory interface with HPI write calls to access the EMIF registers. This can be accomplished with the `evm6x_init_emif()` function (see page 1-26).

3) Load the DSP program with HPI write calls using the `evm6x_coff_load()` function (see page 1-8).

4) Unreset the DSP from its halted state using the `evm6x_unreset_dsp()` function (see page 1-42).

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.
**evm6x_retrieve_message**

**Example**

In the following example, the evm6x_reset_dsp() function places the DSP into HPI boot mode. While in this state, the DSP accepts HPI accesses. The evm6x_unreset_dsp() function releases the DSP from this state and begins execution of DSP code. See the evm6x_unreset_dsp() function example on page 1-42 for more information.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE                  h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

if ( !evm6x_reset_dsp(h_board, HPI_BOOT) )
{
    /* DSP reset call failed */
}
else
{
    /* DSP reset call succeeded */
}
```

**evm6x_retrieve_message**

Retrieves a Message from a DSP

**Syntax**

```c
#include <evm6xdll.h>

BOOL evm6x_retrieve_message(
    HANDLE     h_device,
    PEVM6X_MESSAGE p_message);
```

**Description**

The evm6x_retrieve_message() function retrieves a mailbox message from the target DSP. This function returns FALSE if the mailbox to the host from the DSP is not full.

This is a completely independent mailbox from that used by the evm6x_send_message() function. Also, the receipt of a message from the DSP can be detected by a Win32 event. The interrupt caused by an incoming message signals an event. The name of the event signaled is the string defined in EVM6X_GLOBAL_MESSAGE_EVENT_BASE_NAME with the board index value appended as a decimal number.

- The `h_device` parameter is the handle returned from a successful evm6x_open() call.
- The `p_message` parameter is a pointer to the location to place the message from the DSP.
Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

Example

In the following example, the evm6x_retrieve_message() function checks for and retrieves a 32-bit word sent by the DSP after waiting for the Win32 event signaling a message arrival. If the evm6x_retrieve_message() function fails, then a message has not been sent by the DSP. However, this should not happen in this example because the routine waits for the event signaling a new message before retrieving the message.

```c
#include <windows.h>
#include <stdio.h>
#include <evm6xdll.h>

HANDLE h_board;
HANDLE h_event;
EVM6XDLL_MESSAGE t_message;
int n_board_index;
char s_buffer[80];

n_board_index = 1;
h_board = evm6x_open( n_board_index, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* create event name and open handle to the event */
sprintf( s_buffer, "%s%d",
    EVM6X_GLOBAL_MESSAGE_EVENT_BASE_NAME,
    n_board_index );
h_event = OpenEvent( SYNCHRONIZE, FALSE, s_buffer );

/* wait for event signaling a message from the DSP */
if ( WaitForSingleObject( h_event, INFINITE )
    != WAIT_OBJECT_0 )
{
    /* wait for event failed */
}

/* retrieve message sent by DSP */
if ( !evm6x_retrieve_message( h_board, &t_message ) )
{
    /* evm6x_retrieve_message() failed */
    /* this means that no message is available */
}
else
{
    /* the 32bit value sent by the DSP is in t_message */
}
```
evm6x_send_message

**Sends a Message to a DSP**

**Syntax**

```c
#include <evm6xdll.h>

BOOL evm6x_send_message(
    HANDLE h_device,
    PEVM6X_MESSAGE p_message);
```

**Description**

The `evm6x_send_message()` function sends a mailbox message to the target DSP. This function returns FALSE if the mailbox from the host to the DSP is not empty.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- The `p_message` parameter is a pointer to the message to be sent to the DSP.

**Return Value**

The function returns TRUE or FALSE to indicate the success of the operation.

**Example**

In the following example, the `evm6x_send_message()` function sends a 32-bit value, 0xfeed002f, to a DSP using the mailbox capability of the McEVM board.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE              h_board;
EVM6XDLL_MESSAGE    t_message;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* send message to DSP */
t_message = 0xfeed002f;
if ( !evm6x_send_message( h_board, &t_message ) )
{
    /* evm6x_send_message() failed */
}
```

1-38
Sets the User Board Options

Syntax

```c
#include <evm6xdll.h>

BOOL evm6x_set_board_config(
    HANDLE h_device,
    EVM6XDLL_CLOCK_MODE e_clock_mode,
    EVM6XDLL_ENDIAN_MODE e_endian_mode,
    ULONG user_bits);
```

Description

The `evm6x_set_board_config()` function sets the software configuration for the board. This includes the clock mode, the endian mode, and the user bits. This operation is not required if the hardware DIP switch settings are to be used. If software settings are to be used, this operation must be done before the DSP is reset using the `evm6x_reset_dsp()` function (see page 1-35).

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.

- The `e_clock_mode` enumerated parameter is one of these values:
  - DSP_CLOCK_SBSRAM configures the DSP to run at the maximum speed for SBSRAM accesses
  - DSP_CLOCK_NORMAL configures the DSP to run at the normal clock speed.
  - DSP_CLOCK_AX1 configures the DSP to run at the oscillator A multiply-by-1 clock speed.
  - DSP_CLOCK_BX1 configures the DSP to run at the oscillator B multiply-by-1 clock speed.

- The `e_endian_mode` enumerated parameter is one of these values:
  - LITTLE_ENDIAN_MODE configures the DSP to run in little-endian mode.
  - BIG_ENDIAN_MODE configures the DSP to run in big-endian mode.

- The `user_bits` parameter is the value to be used for the three user bits. If the value is greater than 7, the value is not used. In this case, the hardware DIP switch setting for the user bits is used.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.
In the following example, the `evm6x_set_board_config()` function sets the McEVM board configuration, overriding the hardware DIP switch settings. This must be done before resetting the DSP. In this example, the clock mode is set to `DSP_CLOCK_SBSRAM` mode, which configures the DSP clock to the speed of the SBSRAM. This allows the DSP to access SBSRAM at one clock per access. The endian mode is set to `BIG_ENDIAN_MODE`, which allows the DSP to execute software compiled and linked to run on a big-endian DSP. The user bits are set to 0xff. The user bits set on the hardware DIP switch are used because the user bits value is greater than 7.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE   h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* set board configuration
reset DSP into HPI boot mode
configure emif registers
load COFF executable
unreset DSP */

if ( !evm6x_set_board_config( h_board,
                             DSP_CLOCK_SBSRAM,
                             BIG_ENDIAN_MODE, 0xff ) )
{
    /* evm6x_set_board_config call failed */
}
evm6x_reset_dsp( h_board, HPI_BOOT );
evm6x_init_emif( h_board, NULL );
evm6x_coff_load( h_board, NULL, "example.out", FALSE, FALSE, FALSE );
evm6x_unreset_dsp( h_board );
```
Sets the Transfer Time-Out

Syntax

```c
#include <evm6xdll.h>

BOOL evm6x_set_timeout( 
    HANDLE h_device, 
    ULONG timeout);
```

Description

The `evm6x_set_timeout()` function sets the time-out value for the PCI bus mastering data transfers. If a transfer exceeds this time-out period, the transfer is terminated. The transfer return value indicates how much of the data was transferred.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- The `timeout` parameter is the number of milliseconds to wait before terminating a pending transfer. A value of 0 disables the time-out feature. The default value at driver startup is 0.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

Example

In the following example, the `evm6x_set_timeout()` function sets the bus master transfer time-out value to 5000 ms (or 5 s). This means that any transfer that takes longer than 5 s will terminate, returning the actual number of bytes transferred during the transfer. A transfer stalls when data to or from the DSP is not available.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* set the transfer timeout to 5 seconds */
if ( !evm6x_set_timeout( h_board, 5000 ) )
{
    /* evm6x_set_timeout failed */
}```
Unresets a DSP After Using HPI Boot Mode

Syntax

```c
#include <evm6xdll.h>
BOOL evm6x_unreset_dsp(HANDLE h_device);
```

Description

The `evm6x_unreset_dsp()` function releases the DSP from the halted state invoked by the `evm6x_reset_dsp()` function with the `mode` parameter set to HPI boot (see page 1-35). Use this function in conjunction with an `evm6x_reset_dsp()` call only. The return value indicates the success of the function call.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

Example

In the following example, the `evm6x_unreset_dsp()` function releases the DSP from the halted state that results from resetting the DSP into HPI boot mode.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE    h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
  /* unable to open board */
  exit(-1);
}

/* reset DSP into HPI boot mode */
/* configure emif registers */
/* load COFF executable */
/* unreset DSP */

if ( !evm6x_unreset_dsp( h_board ) )
{
  /* DSP unreset call failed */
}
```
evm6x_user_semaphore_get

**Acquires User Semaphore**

**Syntax**

```c
#include <evm6xdll.h>
BOOL evm6x_user_semaphore_get(  
    HANDLE h_device,  
    PULONG semState);
```

**Description**
The `evm6x_user_semaphore_get` function is used to acquire the user semaphore.

- The `semState` parameter is a pointer to the semaphore.
- The `h_device` parameter is the handle returned from a successful `evm6x_open` call.

**Return Value**
The function returns TRUE or FALSE to indicate the success of the operation.

---

evm6x_user_semaphore_release

**Releases User Semaphore**

**Syntax**

```c
#include <evm6xdll.h>
BOOL evm6x_user_semaphore_release(  
    HANDLE h_device);
```

**Description**
The `evm6x_user_semaphore_release` function is used to release the user semaphore.

- The `h_device` parameter is the handle returned from a successful `evm6x_open` call.

**Return Value**
The function returns TRUE or FALSE to indicate the success of the operation.
evm6x_user_semaphore_wait

Waits Until the Semaphore is Available

Syntax

```c
#include <evm6xdll.h>
BOOL evm6x_user_semaphore_wait(
    HANDLE h_device);
```

Description

The `evm6x_user_semaphore_wait` function is used to wait until the semaphore is available.

- The `h_device` parameter is the handle returned from a successful `evm6x_open` call.

Return Value

The function returns TRUE or FALSE to indicate the success of the operation.

---

evm6x_write

Writes Data to a Board

Syntax

```c
#include <evm6xdll.h>
BOOL evm6x_write(
    HANDLE h_device,
    PULONG p_buffer,
    PULONG p_length);
```

Description

The `evm6x_write()` function transfers data from host memory to the DSP using the PCI bus mastering capability of the board. This transfer can take an indeterminate amount of time, depending on the DSP accepting data for the transfer. To prevent the host from waiting too long for a transfer, a time-out feature is available. Use the `evm6x_set_timeout()` function to set the time-out value (see page 1-41).

Also, a transfer can be terminated at any time using the `evm6x_abort_write()` function (see page 1-3). A transfer that has been timed out or terminated still returns a success indication, but the length value returned is not the same as the originally requested transfer length.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.

- The `p_buffer` parameter is the address of the buffer to be transferred by the write operation. This address must be 32-bit word aligned.

- The `p_length` parameter is the address of the write length. The length is updated with the actual transfer length. The length is the number of bytes
evm6x_write

to be transferred but must be a multiple of 4 because all transfers are 32-bit words.

**Return Value**
The function returns TRUE or FALSE to indicate the success of the operation.

**Example**
In the following example, the evm6x_write() function sends 292 bytes (73 words, 32 bits each) from host memory to the DSP using the PCI FIFO interface provided on the McEVM board. The transfer may succeed, but be incomplete if the transfer timed out or a transfer abort request was initiated from a separate thread. For additional information, see the evm6x_set_timeout() function description on page 1-41 and the evm6x_abort_write() function description on page 1-3.

```c
#include <windows.h>
#include <evm6xdll.h>

HANDLE   h_board;
ULONG    ul_length; /* requested transfer */
          /* length in bytes */
ULONG    ul_ret_len; /* returned transfer */
          /* length in bytes */
ULONG    ul_buffer[1024]; /* data buffer, must */
          /* be 32bit aligned */

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{ /* unable to open board */
    exit(-1);
}

ul_length = 292;
ul_ret_len = ul_length;
if ( !evm6x_write( h_board, ul_buffer, &ul_ret_len ) )
{ /* evm6x_write failed. */
}
else
{
    if ( ul_ret_len != ul_length )
    { /* evm6x_write incomplete */
        /* this can be the result of a time out or */
        /* an abort */
    }
}
```

TMS320C62x McEVM Host Support Software 1-45
1.16 McEVM Host Support Software Example

The following is a simple program that loads and runs a COFF file in the McEVM. The program illustrates the use of a number of the most basic McEVM Win32 DLL calls.

Example 1–1. McEVM Win32 DLL Sample Code

```c
/*–––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––*/
/* FILENAME: HostApp.c -- Host Support Software Example                        */
/*–––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––*/
#include <windows.h>
#include "evm6xdll.h"

void WriteWord2Mem( LPVOID, ULONG, ULONG );
/*–––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––*/
/* main()                                                                     */
/*–––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––––*/
void main(int argc1, char *argv1[])
{
    HANDLE hBd    = NULL; /* Board device handle */
    short  iBd    = 0;    /* Board index */
    BOOL   bExcl  = 1;    /* Exclusive open = TRUE */
    short  iMp    = 0;    /* Map selector = MAP0 */
    EVM6XDLL_BOOT_MODE mode = HPI_BOOT_MAP0;
        /* DSP boot mode */
    LPVOID hHpi   = NULL; /* HPI interface handle */
    char coffNam[] = "blink.out";
        /* COFF file name */
    BOOL bVerbose = 0;    /* COFF load verbose mode = FALSE */
    BOOL bClr     = 0;    /* Clear bss mode = FALSE */
    BOOL bDump    = 0;    /* Dump mode = FALSE */

    hBd = evm6x_open( iBd, bExcl );
    if ( hBd == INVALID_HANDLE_VALUE ) exit(1);

    if ( !evm6x_reset_board(hBd) ) exit(2);

    mode = iMp ? HPI_BOOT : HPI_BOOT_MAP0;
    if ( !evm6x_reset_dsp(hBd,mode) ) exit(3);

    hHpi = evm6x_hpi_open(hBd);
    if ( hHpi == NULL ) exit(4);
```

1-46
/* Initialize EMIF registers */
if ( !evm6x_init_emif(hBd, hHpi) ) exit(5);

/* set Aux DMA priority higher than CPU */
/* Due to the default priority of the auxiliary DMA channel used for */
/* HPI accesses, the CPU can prevent HPI accesses from completing for */
/* an indeterminate amount of time. This can occur when the CPU is */
/* very active on the external memory interface, such as while executing*/
/* code from external memory. This condition manifests itself as a */
/* hung PCI bus. To prevent this condition, the value 0x10 can be */
/* written to the DMA Auxiliary Control Register of the 6201 (at */
/* address 0x01840070). This elevates the priority of the auxiliary */
/* DMA channel above all other DMA channels and above the CPU. */
WriteWord2Mem( hHpi, 0x01840070 /*Addr*/, 0x00000010 /*Data*/ );

/* Read a COFF file and write the data to DSP memory. */
if (!evm6x_coff_load(hBd,hHpi,coffNam,bVerbose,bClr,bDump)) exit(8);

/* Close the HPI session started with evm6x_hpi_open() */
if (!evm6x_hpi_close(hHpi)) exit(9);

/* Release the DSP from the halted state */
if (!evm6x_unreset_dsp(hBd)) exit(10);

/* Close a previously opened driver connection to a board. */
if (!evm6x_close(hBd)) exit(11);
exit(0);

} /* end of main() */

/* Write one word (32 bits) to DSP memory */
void WriteWord2Mem( LPVOID hHpi, ULONG ulDataAddr, ULONG ulDataWord )
{
    ULONG       ulLength;
    ULONG       ulReturnedLength;
    ulLength = 4;
    ulReturnedLength = ulLength;
    if ( !evm6x_hpi_write( hHpi, &ulDataWord, 
                            &ulReturnedLength, ulDataAddr) ) exit(6);
    if ( ulLength != ulReturnedLength ) exit(7);
}
This chapter describes the McEVM DSP support software by providing application programming interfaces (APIs) and example code for the multichannel buffered serial port (McBSP) driver, Multi-Vendor Integration Protocol (MVIP) library, voice-band audio processor (VBAP) library, T1/E1 framer library, and board support library. All of these modules use the TMS320C6000 peripheral support library to access and control internal peripheral registers. See the TMS320C6x Peripheral Support Library Programmer’s Reference for a description of this library.

2.1 DSP Support Software Components

The DSP support software consists of these components:

- McBSP driver
- MVIP library
- Board support library
- FMIC library
- T1/E1 framer library
- VBAP library
- PCI/AMCC library
- C I/O device library

The example code provided operates the MT90810 flexible MVIP integrated circuit (FMIC) in serial data mode, and all telephony data is communicated to and from the 'C62x via the McBSP0. Configuration and control of the MVIP FMIC are achieved via the parallel data interface. These two modules are totally independent of one another in that the MVIP library makes no calls to the McBSP driver and vice-versa. It is your responsibility to configure both peripherals for use and to control them independently. The board support library, on the other hand, is used by both the McBSP driver and the MVIP library.

The McBSP provides two types of routines for sending and receiving data. The synchronous routines mcbsp_sync_send() and mcbsp_sync_receive() transfer data by polling the data transmit ready (DXR) and data receive ready (DRR) bits, respectively, to determine when the next word can be written or read. These routines are referred to as blocking because the CPU is blocked waiting for the transfer to complete before returning control to the caller. The asynchronous routines mcbsp_async_send() and mcbsp_async_receive() use the direct memory access (DMA) engine of the 'C62x to transfer the data in the background. User-supplied callback functions are invoked upon completion of the data transfers to signal the caller. These callback functions are invoked from an interrupt service routine and may set a global flag, for instance, which would indicate data is ready to be processed.

The MVIP library is a collection of routines that configure and control the operation of the MT90810 MVIP FMIC. The API functions correspond closely to the functional organization of the chip. Numerous macros are defined for this library in the file MT90810.h. These macros can be used as arguments to the API functions.

The board support library provides routines for configuring and controlling the McEVM and returning status information to the caller. The module also includes utility functions such as LED control and delay routines.

The FMIC library is a collection of routines that configure and control the operation of the MT90810 FMIC device. The API functions provide low level access, which allows user code to configure the device into any desired configuration.
The API functions also provide higher level access for use in standard device operations.

The T1/E1 Framer library is a collection of routines that configure and control the operation of the Siemens FALC55 (PEB2255) device. The API functions provide low level access, which allows user code to configure the device into any desired configuration. The API functions also provide higher level access for use in standard device operations.

The VBAP library is a collection of routines that control the selection between the μ-law (North American & Japanese) and the A-law (European) companding devices.

The PCI/AMCC library is a collection of routines that provide host communications via the AMCC S5933 device. This driver provides data streams using PCI Bus Mastering and message passing using mailboxes.

The C I/O device library is a collection of routines that provide the required interface between the TI C Compiler’s C I/O support and the PCI/AMCC driver. Using this C I/O device library functions and the add_device() function from the TI C Compiler, DSP code can send and receive data streams with the host using standard C I/O functions such as fprintf() and fgets().
2.2 Using the DSP Support Software Components

The DSP support software, which consists of the McBSP driver, MVIP library, VBAP library, T1/E1 framer library, and board support library, is installed from the accompanying CD-ROM to the \evm6x\dsp\lib\drivers directory. These components are in object format and are supplied in the archived object library file drv6x.lib. Another file, drv6xe.lib, is the big-endian version of the archived object library. The source for the DSP support software is contained in the source library file drv6x.src. To extract the source files, assuming that you have installed the `C62x code generation tools, enter:

\texttt{ar6x -x drv6x.src}

This command extracts the two makefiles in the drv6x.src file. The files makefile and makefile.big are the little- and big-endian makefile versions, respectively. The first two lines of these files must be modified to point to your c6xtools directory and to your `C6000 peripheral support library files. See the \textit{TMS320C6x Peripheral Support Library Programmer’s Reference} for more information about building this library in the desired mode.

To build the object files from the extracted source (*.c) files, enter one of these commands:

\texttt{nmake} \hspace{1cm} \texttt{For little-endian object modules}
\texttt{nmake -fmakefile.big} \hspace{1cm} \texttt{For big-endian object modules}

To rebuild the object library, enter one of these commands:

\texttt{nmake drv6x.lib} \hspace{1cm} \texttt{For little-endian object library}
\texttt{nmake -fmakefile.big drv6xe.lib} \hspace{1cm} \texttt{For big-endian object library}

It is possible to build the file drv6xe.lib with little-endian object files and vice-versa, so use caution when building these libraries. Any attempt to use a library of one endian version with code of another will produce a linker error.

Example code that uses the McBSP driver, MVIP library, VBAP library, T1/E1 framer library, and board support library exists in the \evm6x\dsp\examples directory. Again, the files makefile and makefile.big refer to the little- and big-endian makefiles, respectively. The first two lines of these makefiles must also be modified to point to your c6xtools and `C6000 peripheral support library files. These makefiles also provide an example of how to include the drv6x.lib file on the linker command line for user-developed code. See the \textit{TMS320C6x Assembly Language Tools User’s Guide} for more information about using object libraries.
The provided example code configures and uses the MVIP FMIC, VBAP, and T1/E1 framer devices and the McBSP in numerous configurations, such as loopback, block capture and playback, continuous capture and playback using ping-pong buffering, and continuous tone generation. You can run the example code via the 'C62x McEVM debugger, or you can load the code and allow it to run using the McEVM COFF loader utility (evm6xldr). The print statements that are visible in the debugger command window are not visible on the DOS screen when you use the COFF loader.
2.3 McBSP Driver API

This section discusses the McBSP driver API. Included in this discussion are the macros, data types, and defined functions that comprise the McBSP driver for the 'C62x McEVM board.

2.3.1 McBSP Driver Macros

Table 2–1 lists the macros defined, their values, and a description of each. The API functions that use each macro are also listed. These macros are defined within the public header file mcbspdrv.h. The majority of the macros used by the McBSP driver are defined within the 'C62x device library header file mcbsp.h. These macros are used as bit and bit field values within registers and correspondingly within elements of the driver data types. See the TMS320C6x Peripheral Support Library Programmer’s Reference and the following section for further information.

Table 2–1. McBSP Driver API State Macros

<table>
<thead>
<tr>
<th>Macro</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLOSED</td>
<td>1</td>
<td>Flags McBSP as closed</td>
</tr>
<tr>
<td>OPEN</td>
<td>2</td>
<td>Flags McBSP as open and waiting for control</td>
</tr>
<tr>
<td>BUSY</td>
<td>3</td>
<td>Flags McBSP as busy</td>
</tr>
</tbody>
</table>

Note: These macros are used by all McBSP driver functions.
2.3.2 McBSP Driver Data Types

This section lists the public data types defined by the McBSP driver that are required for accessing McBSP driver functions.

Example 2–1. McBSP Driver API Data Types
(a) McBSP device handle

typedef Mbsp_dev * Mbsp_dev;

An initialized Mbsp_dev is required for all subsequent McBSP driver calls. The data structure Mbsp_dev is used as a private (global static) structure that records state information for each port.

(b) McBSP callback function

typedef void Callback(Mbsp_dev dev, int status);

Callback functions are used by mbsp_async_send() and mbsp_async_receive() to indicate completion of the requested action.

(c) McBSP configuration structure

typedef struct Mbsp_config_struct
{
    int              loopback;
    Mbsp_tx_config  tx;
    Mbsp_rx_config  rx;
    Mbsp_srg_config srg;
}

Mbsp_config;

The Mbsp_config structure is used when calling the mbsp_config() function. The element loopback is TRUE or FALSE and is used to control the data loopback mode. The transmitter, receiver, and sample rate generator configuration values are contained in the three structure elements listed in Example 2–1(d), Example 2–1(e), and Example 2–1(f), respectively.
Example 2–1. McBSP Driver API Data Types (Continued)

d) McBSP transmitter configuration structure

typedef struct Mcbsp_tx_config_struct
{
    unsigned char update; /* Update Tx Parameters? T/F */
    unsigned char interrupt_mode; /* SPCR(2): XRDY, Blk, Frame, SyncErr */
    unsigned char clock_polarity; /* PCR(1): Rise or Fall of CLKX */
    unsigned char frame_sync_polarity; /* PCR(1): Active High or Low */
    unsigned char clock_mode; /* PCR(1): External or Internal */
    unsigned char frame_sync_mode; /* PCR(1): External or Internal */
    unsigned char phase_mode; /* XCR(1): Single or Dual */
    unsigned char frame_length1; /* XCR(7): 1 to 128 wpsf for phase 1 */
    unsigned char frame_length2; /* XCR(7): 1 to 128 wpsf for phase 2 */
    unsigned char word_length1; /* XCR(3): bits per phase 1 word */
    unsigned char word_length2; /* XCR(3): bits per phase 2 word */
    unsigned char companding; /* XCR(2): ALAW ULAW or MSB or LSB */
    unsigned char frame_ignore; /* XCR(1): T/F */
    unsigned char data_delay; /* XCR(3): 0–2 Tx data delay */
    unsigned char dummy[2]; /* pad bytes to 32 bit align */
} Mcbsp_tx_config;

The Mcbsp_tx_config structure is a substructure of Mcbsp_config and is used to assign register values for the transmitter. The corresponding bits and bit field values are shown to the right of each structure element. See the TMS320C6201/C6701 Peripherals Reference Guide for a detailed discussion of each value.
Example 2–1. McBSP Driver API Data Types (Continued)

(e) McBSP receiver configuration structure

```c
typedef struct Mcbsp_rx_config_struct
{
  unsigned char update;    /* Update Rx Parameters? T/F */
  unsigned char interrupt_mode;    /* SPCR(2): RRDY, Blk, Frame, Syncerr */
  unsigned char justification;    /* SPCR(2): RJZF, RJSE or LJZF */
  unsigned char clock_polarity;    /* PCR(1): Rise or Fall of CLKX */
  unsigned char frame_sync_polarity;    /* PCR(1): Active High or Low */
  unsigned char clock_mode;    /* PCR(1): External or Internal */
  unsigned char frame_sync_mode;    /* PCR(1): External or Internal */
  unsigned char phase_mode;    /* XCR(1): Single or Dual */
  unsigned char frame_length1;    /* XCR(7): 1 to 128 wpf for phase 1 */
  unsigned char frame_length2;    /* XCR(7): phase 2 */
  unsigned char word_length1;    /* XCR(3): bits per phase 1 word */
  unsigned char word_length2;    /* XCR(3): bits per phase 2 word */
  unsigned char companding;    /* XCR(2): ALAW, UALAW or MSB or LSB */
  unsigned char frame_ignore;    /* XCR(1): T/F */
  unsigned char data_delay;    /* XCR(3): 0–2 Rx data delay */
  unsigned char dummy;    /* pad bytes */
} Mcbsp_rx_config;
```

The Mcbsp_rx_config structure is a substructure of Mcbsp_config and is used to assign register values for the receiver. The corresponding bits and bit field values are shown to the right of each structure element. See the TMS320C6201/C6701 Peripherals Reference Guide for a detailed discussion of each value.

(f) McBSP sample rate generator configuration structure

```c
typedef struct Mcbsp_srg_config_struct
{
  unsigned char update;    /* Update SRGR Parameters? T/F */
  unsigned char clock_sync;    /* SRGR(1): GSYNC_OFF or GSYNC_ON */
  unsigned char clks_polarity;    /* SRGR(1): rising or falling edge */
  unsigned char clks_mode;    /* SRGR(1): external or internal */
  unsigned char frame_sync_mode;    /* SRGR(1): FSX due to DXR–XSR, FSG */
  unsigned short frame_period;    /* SRGR(12): Frame period 1–4096 */
  unsigned char frame_width;    /* SRGR(8): 1 to 256 CLKG periods */
  unsigned char clock_divider;    /* SRGR(8): SRGR clock dvdr: 1–256 */
} Mcbsp_srg_config;
```

The Mcbsp_srg_config structure is a substructure of Mcbsp_config and is used to assign register values for the receiver. The corresponding bits and bit field values are shown to the right of each structure element. See the TMS320C6201/C6701 Peripherals Reference Guide for a detailed discussion of each value.
### 2.3.3 McBSP Driver Functions

The following alphabetical listing includes all of the McBSP driver API functions. Use this listing as a table of contents to the McBSP driver API functions.

Receives a Buffer of Data on the Selected McBSP Asynchronously

### Syntax

```c
#include <mcbspdrv.h>

int mcbsp_async_receive(
    Mcbsp_dev dev,
    unsigned char *p_buffer,
    unsigned int num_bytes,
    unsigned int frame_sync_enable,
    Mcbsp_dev frame_sync_dev,
    Callback *p_ract);
```

### Defined in
mcbspdrv.c as a callable C routine

### Description
The `mcbsp_async_receive()` function receives a buffer of data from the indicated McBSP in an asynchronous (also known as nonblocking) manner. This routine transfers data in the background using an available direct memory access (DMA) engine. An interrupt service routine is set up by this routine; once the indicated number of bytes has been transferred, the BLOCK COND bit in the DMA secondary control register triggers the enabled DMA interrupt. This interrupt service routine can call a user-supplied callback function, which could, for example, be used to set a global transfer flag indicating that reception is finished. You do not have access to the interrupt service routine, only the callback function to which you provide a pointer.

- Parameter `dev` refers to the initialized device handle returned by the `mcbsp_open()` call.
- The `p_buffer` parameter is a pointer to the buffer used to hold received data.
- The `num_bytes` parameter refers to the number of bytes to receive. Typically, the McBSP is configured for 32-bit transfers. In this case, `num_bytes` is four times the number of 32-bit elements to receive. You must ensure that the buffer pointed to by `p_buffer` is at least as large as `num_bytes`.
- The `frame_sync_enable` parameter is used to enable the internal frame sync generator. Valid values are `TRUE` or `FALSE`.
- The `frame_sync_dev` parameter indicates which port’s frame sync generator to enable. If `frame_sync_enable` is `FALSE`, set `frame_sync_dev` to `NULL`. In most cases, `frame_sync_dev` is the same as `dev`.
- The `p_ract` parameter is a pointer to the user-supplied callback function. See section 2.3.2, McBSP Driver Data Types, for the typedef `Callback`, which defines the structure of the callback function.
mcbsp_async_receive

Return Value
The function returns one of the following values:

OK Transfer setup succeeded
ERROR Transfer setup failed

Example
The following code provides an example invocation assuming that the driver
has been initialized and the device has been opened and configured for an ex-
ternal frame sync and 32-bit transfers.

```c
#define NUM_WORDS 128

Callback callback_function(Mcbsp_dev dev, int status) {    
    printf("Data transfer for mcbsp_async_receive() completed 
            with status = \%d\n", status); 
    return;
}

int status;
unsigned int buffer[NUM_WORDS];

status = mcbsp_async_receive(dev0, 
                              buffer, 
                              NUM_WORDS * sizeof(int), 
                              FALSE, 
                              NULL, 
                              callback_function)

if (status == ERROR) {    
    printf("Error setting up data transfer with 
            mcbsp_sync_receive()\n"); 
    return (ERROR);
}
```
**mcbsp_async_send**

Sends a Buffer of Data on the Selected McBSP Asynchronously

### Syntax

```c
#include <mcbspdrv.h>

int mcbsp_async_send(
    Mcbsp_dev dev,
    unsigned char *p_buffer,
    unsigned int num_bytes,
    unsigned int frame_sync_enable,
    Mcbsp_dev frame_sync_dev,
    Callback *p_wact);
```

### Defined in

mcbspdrv.c as a callable C routine

### Description

The `mcbsp_async_send()` function sends a buffer of data from the indicated McBSP in an asynchronous (also known as nonblocking) manner. This routine transfers data in the background using an available DMA engine. An interrupt service routine is set up by this routine; once the indicated number of bytes have been transferred, the BLOCK COND bit in the DMA secondary control register triggers the enabled DMA interrupt. This interrupt service routine can call a user-supplied callback function, which could, for example, be used to set a global transfer flag indicating that transmission is finished. You do not have access to the interrupt service routine, only the callback function to which you provide a pointer.

- The `dev` parameter refers to the initialized device handle returned by the `mcbsp_open()` call.
- The `p_buffer` parameter is a pointer to the buffer used to hold data to be transmitted.
- The `num_bytes` parameter refers to the number of bytes to send. Typically, the McBSP is configured for 32-bit transfers. In this case, `num_bytes` is four times the number of 32-bit elements to receive.
- The `frame_sync_enable` parameter is used to enable the internal frame sync generator. Valid values are TRUE or FALSE.
- The `frame_sync_dev` parameter indicates which port’s frame sync generator to enable. If `frame_sync_enable` is FALSE, set `frame_sync_dev` to NULL. In most cases, `frame_sync_dev` is the same as `dev`.
- The `p_wact` parameter is a pointer to the user-supplied callback function. See section 2.3.2, McBSP Driver Data Types, for the typedef `Callback`, which defines the structure of the callback function.
**mcbsp_close**

**Return Value**
The function returns one of the following values:

- **OK** Transfer setup succeeded
- **ERROR** Transfer setup failed

**Example**
The following code provides an example invocation assuming that the driver has been initialized and the device has been opened and configured for an internal frame sync and 32-bit transfers.

```c
#define NUM_WORDS 128
Callback callback_function(Mcbsp_dev dev, int status)
{
    printf("Data transfer for mcbsp_async_send() completed with status = %d\n", status);
    return;
}

int status;
unsigned int buffer[NUM_WORDS];
status= mcbsp_async_send(dev0, buffer, NUM_WORDS * sizeof(int), TRUE, dev0,
                         callback_function);

if (status == ERROR)
{
    printf("Error setting up data transfer with \nmcbsp_sync_send()\n");
    return(ERROR);
}
```

**mcbsp_close**

*Closes the Selected McBSP/Release the Device Handle*

**Syntax**

```c
#include <mcbspdrv.h>
void mcbsp_close(Mcbsp_dev dev);
```

**Defined in**

mcbspdrv.c as a callable C routine

**Description**
The mcbsp_close() function closes the selected McBSP and releases its associated device handle structure.

- The `dev` parameter is the device handle that was initialized by the mcbsp_open() call.

**Return Value**
None

**Example**
The code in this example closes the McBSP associated with `dev`, allowing another routine or thread to control its operation.

```c
mcbsp_close(dev);
```
mcbsp_config

Configures the Selected McBSP

Syntax

```c
#include <mcbspdrv.h>
int mcbsp_config(
    Mcbsp_dev dev,
    Mcbsp_config *p_mcbsp_config);
```

Defined in

mcbspdrv.c as a callable C routine

Description

The mcbsp_config() function configures the selected McBSP. Configuration values are passed to this routine via the Mcbsp_config structure (see section 2.3.2, McBSP Driver Data Types, for the definition of this structure). The macro defines for the configuration structure elements are defined in the file mcbsp.h, which is part of the 'C6000 device library.

- The `dev` parameter refers to the initialized device handle returned by the mcbsp_open() call.
- The `p_mcbsp_config` parameter is a pointer to a user-initialized McBSP configuration structure.

Return Value

The function returns one of the following values:

- **OK**  Configuration values are within range of their respective min/max values.
- **ERROR**  Configuration values were greater than or less than their respective min/max values.

Example

The code in this example configures the transmitter, receiver, and sample rate generator for the McBSP associated with the initialized device handle `dev` for use in internal loopback mode. Defines shown in this example are part of the 'C6000 peripheral control library.

```c
config.loopback              = TRUE;
config.tx.update             = TRUE;
config.tx.clock_polarity     = CLKX_POL_RISING;
config.tx.frame_sync_polarity= FSYNC_POL_HIGH;
config.tx.clock_mode         = CLK_MODE_INT;
config.tx.frame_sync_mode    = FSYNC_MODE_INT;
config.tx.phase_mode         = SINGLE_PHASE;
config.tx.frame_length1      = 0;
config.tx.word_length1       = WORD_LENGTH_32;
config.tx.frame_ignore       = NO_FRAME_IGNORE;
config.tx.data_delay         = DATA_DELAY1;
config.rx.update             = TRUE;
config.rx.clock_polarity     = CLKR_POL_FALLING;
config.rx.frame_sync_polarity= FSYNC_POL_HIGH;
config.rx.clock_mode         = CLK_MODE_EXT;
config.rx.frame_sync_mode    = FSYNC_MODE_EXT;
```
mcbsp_cont_async_send

config.rx.phase_mode = SINGLE_PHASE;
config.rx.frame_length1 = 0;
config.rx.word_length1 = WORD_LENGTH_32;
config.rx.frame_ignore = NO_FRAME_IGNORE;
config.rx.data_delay = DATA_DELAY1;
config.srg.update = TRUE;
config.srg.clks_mode = CLK_MODE_INT;
config.srg.frame_sync_mode = FSX_DXR_TO_XSR;
config.srg.frame_width = 1;
config.srg.clock_divider = 0xff;
if (mcbsp_config(dev0,&config))
{
    printf("Error returned from mcbsp_config() for dev0");
    mcbsp_close(dev0);
    return(ERROR);
}

mcbsp_cont_async_send

Continuously Sends a Buffer of Data on the Selected McBSP

Syntax
#include <mcbspdrv.h>

int mcbsp_cont_async_send(
    Mcbsp_dev dev,
    unsigned char *p_ping_buff,
    unsigned char *p_pong_buff,
    unsigned int num_bytes,
    unsigned int frame_sync_enable,
    int McBSP_dev frame_sync_dev,
    Callback *p_wact);

Defined in
mcbspdrv.c as a callable C routine

Description
The mcbsp_cont_async_send() function repeatedly sends either a single
buffer or a ping-pong type buffer in an asynchronous (also known as nonblock-
ing) manner. This routine transfers data in the background using an available
DMA engine. An interrupt service routine is set up by this routine; once the indi-
cated number of bytes have been transferred, the BLOCK COND bit in the
DMA secondary control register triggers the enabled DMA interrupt. This inter-
rupt service routine can call a user-supplied callback function, which could, for
example, be used to set a global transfer flag indicating another transmission
is finished. You do not have access to the interrupt service routine, only the
callback function to which you provide a pointer.

- The dev parameter refers to the initialized device handle returned by the
  mcbsp_open() call.
- The p_ping_buffer parameter is a pointer to the buffer used to hold data
to be transmitted.
The $p\_pong\_buffer$ parameter is a pointer to the secondary transmit buffer. If this parameter is NULL, the data in $p\_ping\_buffer$ is continuously sent. If this parameter is valid, data transmission ping-pongs between these two buffers.

The $num\_bytes$ parameter refers to the number of bytes to send (same for each buffer). Typically, the McBSP is configured for 32-bit transfers. In this case, $num\_bytes$ is four times the number of 32-bit elements to receive.

The $frame\_sync\_enable$ parameter is used to enable the internal frame sync generator. Valid values are TRUE or FALSE.

The $frame\_sync\_dev$ parameter indicates which port's frame sync generator to enable. If $frame\_sync\_enable$ is FALSE, set $frame\_sync\_dev$ to NULL. In most cases, $frame\_sync\_dev$ is the same as $dev$.

The $p\_wact$ parameter is a pointer to the user-supplied callback function. See section 2.3.2, McBSP Driver Data Types, for the typedef Callback, which defines the structure of the callback function.

**Return Value**

The function returns one of the following values:

- **OK** Transfer setup succeeded
- **ERROR** Transfer setup failed

**Example**

The following code provides an example invocation assuming that the driver has been initialized and the device has been opened and configured for an internal frame sync and 32-bit transfers. This code continuously sends 16 buffers of data, eight from the $ping\_buff[]$ and eight from the $pong\_buff[]$. To turn off continuous operation, the callback function must set $dev->tx\_dma.continuous$ to FALSE one block before transmission should stop.

```c
#define NUM_WORDS    128
#define NUM_BUFFS    16
int     num_buffs_sent=    0;

Callback  callback_function(    Mbsp_dev dev,
   int       status)
{
   printf("Data transfer for mbsp_async_send() completed
   with\ status = %d\n",status);
   num_buffs_sent++;
   if (num_buffs_sent == NUM_BUFFS)
      mbsp_stop(dev);
   return;
}

int          status;
unsigned int ping_buff[NUM_WORDS];
unsigned int pong_buff[NUM_WORDS];
```
for (i=0;i<NUM_WORDS;i++) /* create a ramp * /
    ping_buff[i] = i;
for (i=0;i<NUM_WORDS;i++) /* create a ramp * /
    pong_buff[i] = i;
status = mcbsp_cont_async_send( dev0,
    ping_buff,
    pong_buff,
    NUM_WORDS * sizeof(int),
    TRUE,
    dev0,
    callback_function
    )
if (status == ERROR)
{
    printf("Error setting up data transfer with \ 
            mcbsp_sync_send()\n");
    return (ERROR);
}

### mcbsp_drv_init

Initialize the McBSP Driver

**Syntax**

```
#include <mcbspdrv.h>
int mcbsp_drv_init(void);
```

**Defined in**

mcbspdrv.c as a callable C routine

**Description**

The `mcbsp_drv_init()` function initializes the McBSP driver for use and must be called before any other driver calls. This function allocates memory for the port 0 and port 1 device handles and initializes structure elements to their default values.

**Return Value**

The function returns one of the following values:

- OK Memory allocation succeeded
- ERROR Memory allocation failed

Subsequent calls to this function simply return OK.

**Example**

The code in this example initializes the McBSP driver for use and is called before any other McBSP routines.

```c
int status;
status = mcbsp_drv_init();
if (status == ERROR)
{
    printf("Error initializing the McBSP driver\n");
    return (ERROR);
}
```

2-18
**mcbsp_open**

*Opens the Selected McBSP/Obtain a Device Handle*

**Syntax**

```c
#include <mcbspdrv.h>

Mcbsp_dev mcbsp_open(int port);
```

**Defined in**

mcbspdrv.c as a callable C routine

**Description**

The `mcbsp_open()` function opens the selected McBSP for use. All subsequent driver calls require an initialized `Mcbsp_dev` argument.

- The `port` parameter indicates which serial port to open, with valid values of 0 or 1.

**Return Value**

The function returns one of the following values:

- `Mcbsp_dev` A valid device handle value is returned if the indicated `port` is not already in use.
- `NULL` The indicated `port` is already in use.

**Example**

The code in this example obtains a device handle for the McBSP port 0. This device handle is required in subsequent McBSP calls, such as `mcbsp_config()` and `mcbsp_async_receive()`.

```c
Mcbsp_dev dev0;
dev0 = mcbsp_open(0);
if (dev0 == NULL)
{
    printf("Unable to obtain a device handle for McBSP 0.");
    return(ERROR);
}
```
mcbsp_reset

Resets the Selected McBSP

Syntax
#include <mcbspdrv.h>
void mcbsp_reset(Mcbsp_dev dev);

Defined in
mcbspdrv.c as a callable C routine

Description
The mcbsp_reset() function simply resets the selected McBSP associated with dev to its default state.

- The dev parameter refers to the initialized device handle returned by the mcbsp_open() call.

Return Value
The function returns one of the following values:
- OK: The dev parameter was supplied as a valid device handle.
- ERROR: The dev parameter was not supplied as a valid device handle.

Example
The code in this example resets the associated McBSP to its default state.

if ( mcbsp_reset( dev ) )
{
    printf("Invalid device handle passed to mcbsp_reset\n");
    return(ERROR);
}

mcbsp_stop

Stops Operation of the Selected McBSP

Syntax
#include <mcbspdrv.h>
void mcbsp_stop(Mcbsp_dev dev);

Defined in
mcbspdrv.c as a callable C routine

Description
The mcbsp_stop() function completely disables the selected McBSP. Both the transmit and receive sections are disabled, as well as the sample rate and frame sync generators.

- The dev parameter refers to the initialized device handle returned by the mcbsp_open() call.

Return Value
None

Example
The code in this example disables the selected McBSP.

mcbsp_stop(dev);
mcbsp_sync_receive

Receives a Buffer of Data on the Selected McBSP Synchronously

Syntax

```c
#include <mcbspdrv.h>
int mcbsp_sync_receive(
    Mcbsp_dev dev,
    unsigned char *p_buffer,
    unsigned int num_bytes,
    unsigned int frame_sync_enable,
    Mcbsp_dev frame_sync_dev,
    int pack_data);
```

Defined in mcbspdrv.c as a callable C routine

Description

The mcbsp_sync_receive() function receives a buffer of data from the indicated McBSP in a synchronous (also known as blocking) manner. During data reception, the CPU is busy polling the data receive ready (DRR) flag in the serial port control register to determine when the next data word is available. Once the indicated number of bytes have been transferred to the buffer, this routine returns to the caller.

- The `dev` parameter refers to the initialized device handle returned by the mcbsp_open() call.
- The `p_buffer` parameter is a pointer to the buffer used to hold received data.
- The `num_bytes` parameter refers to the number of bytes to receive. Typically, the McBSP is configured for 32-bit transfers. In this case, `num_bytes` is four times the number of 32-bit elements to receive. You must ensure that the buffer pointed to by `p_buffer` is at least as large as `num_bytes`.
- The `frame_sync_enable` parameter is used to enable the internal frame sync generator. Valid values are TRUE or FALSE.
- The `frame_sync_dev` parameter indicates which port’s frame sync generator to enable. If `frame_sync_enable` is FALSE, set `frame_sync_dev` to NULL. In most cases, `frame_sync_dev` is the same as `dev`.
- Parameter `pack_data` can be used to pack received elements that are less than 32 bits into `p_buffer`. Valid values for `pack_data` are TRUE or FALSE. The `pack_data` feature can only be used when the serial port is configured for single-phase transfers.

Return Value

The function returns one of the following values:

- OK Transfer succeeded
- ERROR Transfer failed
mcbsp_sync_send

Example

The following code provides an example invocation assuming that the driver has been initialized and the device has been opened and configured for an external frame sync and 32-bit transfers.

```
#define NUM_WORDS     128
int          status;
unsigned int buffer[NUM_WORDS];
status= mcbsp_sync_receive( dev0,
                           buffer,
                           NUM_WORDS * sizeof(int),
                           FALSE,
                           NULL,
                           FALSE);
```

if (status == ERROR)
{
    printf("Error receiving data with mcbsp_sync_receive()\n");
    return(ERROR);
}

Sends a Buffer of Data on the Selected McBSP Synchronously

Syntax

```
#include <mcbspdrv.h>
int mcbsp_sync_send(
    Mcbsp_dev dev,
    unsigned char *p_buffer,
    unsigned int num_bytes,
    unsigned int frame_sync_enable,
    Mcbsp_dev frame_sync_dev,
    int packed_data);
```

Defined in

mcbspdrv.c as a callable C routine

Description

The mcbsp_sync_send() function sends a buffer of data across the indicated McBSP in a synchronous (also known as blocking) manner. During data transmission, the CPU is busy polling the data transmit ready (DXR) flag in the serial port control register to determine when the next element can be written. Once the indicated number of bytes have been transferred from the buffer, this routine returns to the caller.

- The dev parameter refers to the initialized device handle returned by the mcbsp_open() call.
- The p_buffer parameter is a pointer to the buffer initialized with the data to send.
mcbsp_sync_send

- The `num_bytes` parameter refers to the number of bytes to send. Typically, the McBSP is configured for 32-bit transfers. In this case, `num_bytes` is four times the number of 32-bit elements to send.

- The `frame_sync_enable` parameter is used to enable the internal frame sync generator. Valid values are TRUE or FALSE.

- The `frame_sync_dev` parameter indicates which port’s frame sync generator to enable. If `frame_sync_enable` is FALSE, set `frame_sync_dev` to NULL. In most cases, `frame_sync_dev` is the same as `dev`.

- The `packed_data` parameter, if TRUE, indicates that the data in `p_buffer` is packed. For element transfers of less than 32 bits, this routine sends only the significant bits for each transfer, sign extended and justified as indicated in the `mcbsp_config()` call (see page 2-15).

Return Value
The function returns one of the following values:

- OK Transfer succeeded
- ERROR Transfer failed

Example
The following code provides an example invocation assuming that the driver has been initialized and the device has been opened and configured for an internal frame sync (FSG) and 32-bit transfers.

```c
#define NUM_WORDS 128
int status;
unsigned int buffer[NUM_WORDS];
for (i=0;i<NUM_WORDS;i++)  /* generate ramp */
    buffer[i]= i;

status= mcbsp_sync_send( dev0,
                          buffer,
                          NUM_WORDS * sizeof(int),
                          TRUE,
                          dev0,
                          FALSE);

if (status == ERROR)
{
    printf("Error sending data with mcbsp_sync_send()\n");
    return(ERROR);
}
```
2.4 FMIC Support Library API

This section discusses the Flexible MVIP Interface Circuit (FMIC) library. Included in this discussion are the macros, data types, and defined functions that comprise the FMIC driver for the ˚C62x McEVM board.

2.4.1 FMIC Driver Macros

Table 2–2 lists the macros defined, their values, and a description of each. The SPI functions that use each macro are also listed. These macros are defined within the public header file fmic.h.

Table 2–2. FMIC Driver API State Macros

<table>
<thead>

Note: These macros are used by Fmic_configure, fmic_read, and fmic_write.
2.4.2 FMIC Driver Data Types

This section lists the public data types defined by the FMIC driver that are required for accessing FMIC driver functions.

Example 2–2. FMIC Driver API Data Types

(a) FMIC device handle

```c
typedef FMIC_DEV *FMIC_DEV_T;
```

An initialized FMIC_DEV handle is required for all subsequent FMIC driver calls. The data structure FMIC_DEV_T is used as a private (global static) structure that records state information for each device.

(b) FMIC configuration structure

```c
typedef struct
{
  fmic_state state;
  u32 base_addr;
}
FMIC_DEV;
```

The FMIC private structure records state information for each device.

2.4.3 FMIC Library API Functions

The following alphabetical listing includes all of the FMIC library API functions. Use this listing as a table of contents to the FMIC library API functions.

<table>
<thead>
<tr>
<th>Function</th>

**fmic_clear_connections**  
_Clears All Connections, Disable All MVIP Channel Outputs_

**Syntax**
```
#include <fmic.h>
int fmic_clear_connections(FMIC_DEV_T fmic_dev);
```

**Defined in**  
fmic.c as a callable C routine

**Description**
This function breaks all input output connections by clearing the connection memory for all MVIP and local channels for the specified FMIC device.

- The `fmic_dev` parameter is a pointer to a structure containing addressing and state information for the FMIC device.

**Return Value**
The function returns one of the following values:
- **OK**  Operation succeeded
- **ERROR**  Operation failed

**Example**
The following example clears all connections on FMIC device dev0.
```
int status;

status = fmic_clear_connections(dev0);
if (status == ERROR)
  return(ERROR);
```

---

**fmic_close**  
_De-initializes Software Driver_

**Syntax**
```
#include <fmic.h>
int fmic_close(FMIC_DEV_T fmic_dev);
```

**Defined in**  
fmic.c as a callable C routine

**Description**
This function removes the handle to the specified FMIC device and resets device information to a default condition.

- `fmic_dev` is a pointer to a structure containing addressing and state information for the FMIC device.

**Return Value**
The function returns one of the following values:
- **OK**  Operation succeeded
- **ERROR**  Operation failed
Example

The following example releases the FMIC device dev0.

```c
int status;
status = fmic_close(dev0);
if (status == ERROR)
    return(ERROR);
```

### fmic_configure

**Configures an FMIC Device**

#### Syntax

```c
#include "fmic.h"
int fmic_configure(
    FMIC_DEV_T     fmic_dev,
    unsigned int  fmic_configuration[3]);
```

#### Defined in

fmic.c as a callable C routine

#### Description

This function configures the specified FMIC device given an input array of register, value and mask sets. The function will write each configuration set in the array to the FMIC device until the mask element becomes zero. This will terminate the configuration.

- `Fmic_dev` is a pointer to a structure containing addressing and state information for the FMIC device.

- `Fmic_configuration` is an array of three element sets consisting of the following information:
  - `Fmic_configuration[0]` = register_id
  - `Fmic_configuration[1]` = value
  - `Fmic_configuration[2]` = mask
  - While mask is non-zero, write the configuration to the FMIC.
  - See the `fmic_write` description for possible values of register_id, value and mask.

#### Return Value

The function returns one of the following values:

- **OK** Operation succeeded
- **ERROR** Operation failed
Example

The following is a generalized example of the use of the `fmic_configure` function. It illustrates making multiple configuration changes with one call. It also illustrates the use of direct and indirect addressing for `register_id` (see `fmic_write()` for further description). The first configuration command sets the RESET bit in the master Control/Status register without affecting any other bits. The second configuration command inverts the 4.096MHz CLK4 clock output pin by setting bit 3 of the Local Clock Control register (indirect offset 1 in the FMIC control register). The third and fourth configuration commands make a connection from output 56 to input 34 while enabling output 56.

```c
int status;
unsigned int fmic_configuration[5][3] = {
    {FMIC_MASTER_REG_ID, 0x1, 0x1 },
    {FMIC_CNTRL_REG_ID | 1, 0x4, 0x4 },
    {FMIC_CONN_MEM_LOW_ID | 56, 34, 0xff},
    {FMIC_CONN_MEM_HIGH_ID | 56, 2, 0xff},
    {0,0,0}
};

status = fmic_configure(dev0, fmic_configuration);
if (status == ERROR)
    return(ERROR);
```

---

`fmic_connect`

**Connects an Input Channel to an Output Channel**

**Syntax**

```
#include "fmic.h"
int fmic_connect(FMIC_DEV_T fmic_dev, unsigned int out_chan, unsigned int in_chan);
```

**Defined in**

`fmic.c` as a callable C routine

**Description**

This function makes a connection between one of 384 input channels and one of 384 output channels on the specified FMIC. For a bidirectional connection, two separate calls should be made reversing the input/output channel combination on the second call.

- `Fmic_dev` is a pointer to a structure containing addressing and state information for the FMIC device.
**fmic_direction**

- Out_chan is a zero relative input channel number from 0 to 383.
- In_chan is a zero relative output channel number from 0 to 383.

**Return Value**
The function returns one of the following values:
- OK Operation succeeded
- ERROR Operation failed

**Example**
The following example makes a bidirectional connection between channels 56 and 34.

```c
int status=0;
status = fmic_connect(dev0, 56, 34);
status |= fmic_connect(dev0, 34, 56);
if (status == ERROR)
    return(ERROR);
```

---

**Selects MVIP Inbound Source For the Specified Channel**

**Syntax**
```c
#include "fmic.h"
int fmic_direction(
    FMIC_DEV_T fmic_dev,
    unsigned int channel,
    fmic_mvip_direction direction);
```

**Defined in**
fmic.c as a callable C routine

**Description**
This function sets the direction of an associated DSi-DSo channel pair. If the DSi or DSo channel is programmed as an input, the corresponding DSo or DSi channel will automatically be configured as an output.

- The fmic_dev parameter is a pointer to a structure containing addressing and state information for the FMIC device.
- The channel parameter is the channel number from 0 to 255.
- The direction parameter selects the inbound source, (DSi, DSo) for the specified channel. It can be one of the following values.
  - FMIC_DSo_IN selects DSo as input for the specified channel.
  - FMIC_DSi_IN selects DSi as input for the specified channel.
Return Value

The function returns one of the following values:

- **OK**: Operation succeeded
- **ERROR**: Operation failed

Example

The following example selects DSo as the input for channel 56. Consequently, DSi will automatically be set as the output for channel 56.

```c
int status;
status = fmic_direction(dev0, 56, FMIC_DSo_IN);
if (status == ERROR)
    return(ERROR);
```

---

**fmic_init**

*Establishes Normal Operating Register and Memory Values*

**Syntax**

```c
#include "fmic.h"
int fmic_init(
    FMIC_DEV_T fmic_dev,
    fmic_timing_mode timing_mode)
```

**Defined in**

fmic.c as a callable C routine

**Description**

This function initializes the specified FMIC device by: returning all register values to reset condition, clearing connection and data ram, establishing normal operating register values and establishing requested timing mode.

- **Fmic_dev** is a pointer to a structure containing addressing and state information for the FMIC device.
- **Timing_mode** selects which clock source is used to generate MVIP clock signals. It can be one of the following values.
  - **FMIC_MVIP_SLAVE** selects the FMIC as timing slave to the MVIP bus.
  - **FMIC_T1E1_MVIP_MASTER** selects the FMIC as timing master.
  - **FMIC_8KMASTER_MVIP_SLAVE** selects the FMIC as timing slave to the MVIP bus.
  - **FMIC_8KSLAVE_MVIP_MASTER** selects the FMIC as timing master.
  - **FMIC_T1E1_8K_MVIP_MASTER** selects the FMIC as timing master.
Return Value

The function returns one of the following values:

- **OK**: Operation succeeded
- **ERROR**: Operation failed

Example

The following example initializes FMIC device dev0 and sets the timing mode to FMIC_MVIP_SLAVE.

```c
int status;
status = fmic_init(dev0, FMIC_MVIP_SLAVE);
if (status == ERROR)
    return ERROR;
```

### fmic_open

**Initializes the Software Driver for an FMIC Device**

**Syntax**

```c
#include "fmic.h"
FMIC_DEV_T fmic_open(unsigned int fmic_base_addr);
```

**Defined in**

fmic.c as a callable C routine

**Description**

This function creates a handle to the FMIC device located at the specified address.

- **Fmic_base_addr** is the base address for the FMIC device to be opened.

**Return Value**

Returns nonzero value as handle.

**Example**

The following nonzero example opens the FMIC device on a McEVM board.

```c
FMIC_DEV_T dev0;
dev0 = fmic_open(FMIC_MOTHER_BASE);
if (dev0 == NULL)
    return ERROR;
```
fmic_output_control

Enables MVIP Output Driver for the Specified Channel

Syntax

```c
#include "fmic.h"

int fmic_output_control
    (FMIC_DEV_T fmic_dev,
     unsigned int channel,
     boolean enable);
```

Defined in

fmic.c as a callable C routine

Description

This function enables and disables output for the specified MVIP channels on the specified FMIC device.

- Fmic_dev is a pointer to a structure containing addressing and state information for the FMIC device.
- Channel specified the output channel from 0 to 255 on the MVIP bus to disable or enable
- Enable specifies whether the indicated channel is to be enabled. The possible values are:
  - TRUE
  - FALSE

Return Value

The function returns one of the following values:

- OK Operation succeeded
- ERROR Operation failed

Example

The following example enables the output for channel 56 on the FMIC device dev0.

```c
int status;
status = fmic_output_control(dev0, 56, TRUE);
if (status == ERROR)
    return(ERROR);
```
**fmic_read**

**Reads the Value at the FMIC Memory/Register Location**

**Syntax**

```c
#include "fmic.h"

unsigned int fmic_read(
    FMIC_DEV_T fmic_dev,
    unsigned int register_id);
```

**Defined in**

`fmic.c` as a callable C routine

**Description**

This function returns the value contained in the indicated FMIC memory/register location on the specified FMIC device.

- `Fmic_dev` is a pointer to a structure containing addressing and state information for the FMIC device.
- `Register_id` is an identifier for either a direct or indirect register/memory location on the FMIC device. For an indirect location, the following indirect IDs should be OR'ed with the desired location in the register/memory space indicated to obtain the value to pass in as `register_id`. For example, to obtain the low byte of the 4th element in the connection memory, `register_id = FMIC_CONN_MEM_LOW_ID | 3`. A direct register does not need an offset and can be used as is. The possible register/memory IDs are defined as follows.

  - `FMIC_MASTER_REG_ID` selects the master control/status register (direct).
  - `FMIC_CNTRL_REG_ID` selects the FMIC control registers (indirect).
  - `FMIC_DATA_MEMORY_ID` selects the data memory (indirect).
  - `FMIC_CONN_MEM_LOW_ID` selects the low byte of the connection memory (indirect).
  - `FMIC_CONN_MEM_HIGH_ID` selects the high byte of the connection memory (indirect).

**Return Value**

Returns the value at the given `register_id`.

**Example**

The following example reads the value in the master control register. It also reads and reconstructs the input connected to output 56 from the connection memory.

```c
unsigned int mcrValue;
unsigned int connValue;

mcrValue = fmic_read(dev0, FMIC_MASTER_REG_ID);
connValue = fmic_read(dev0, FMIC_CONN_MEM_LOW_ID | 56);
connValue |= (fmic_read(dev0, FMIC_CONN_MEM_HIGH_ID | 56)) << 8) & 0x100;
```
**fmic_timing**

*Establish Requested Timing Mode*

**Syntax**

```c
#include "fmic.h"

int fmic_timing(
    FMIC_DEV_T fmic_dev,
    fmic_timing_mode timing_mode);
```

**Defined in**

fmic.c as a callable C routine

**Description**

This function establishes clock control functionality for the indicated FMIC device.

- `fmic_dev` is a pointer to a structure containing addressing and state information for the FMIC device.
- `timing_mode` selects which clock source is used to generate MVIP clock signals. It can be one of the following values:
  - `FMIC_MVIP_SLAVE` selects the FMIC as timing slave to the MVIP bus.
  - `FMIC_T1E1_MVIP_MASTER` selects the FMIC as timing master.
  - `FMIC_8KMASTER_MVIP_SLAVE` selects the FMIC as timing slave to the MVIP bus.
  - `FMIC_8KSLAVE_MVIP_MASTER` selects the FMIC as timing master.
  - `FMIC_T1E1_8K_MVIP_MASTER` selects the FMIC as timing master.

**Return Value**

The function returns one of the following values:

- `OK` Operation succeeded
- `ERROR` Operation failed

**Example**

The following example sets the timing mode of the FMIC device `dev0` to `FMIC_MVIP_SLAVE`.

```c
int status;

status = fmic_timing(dev0, FMIC_MVIP_SLAVE);
if (status == ERROR)
    return(ERROR);
```
**fmic_write**

*Writes a Value to the Indicated FMIC Register/Memory Location*

**Syntax**

```c
#include "fmic.h"
int fmic_write(
    FMIC_DEV_T fmic_dev,
    unsigned int register_id,
    unsigned int value,
    unsigned int mask);
```

**Defined in**

fmic.c as a callable C routine

**Description**

This function writes a value to the indicated register/memory location on the specified FMIC device. The write will only affect bit values of the indicated register/memory location set in the mask.

- Fmic_dev is a pointer to a structure containing addressing and state information for the FMIC device.

- Register_id is an identifier for either a direct or indirect register/memory location on the FMIC device. For an indirect location, the following indirect IDs should be OR'ed with the desired location in the register/memory space indicated to obtain the value to pass in as register_id. For example, to obtain the low byte of the 4th element in the connection memory, register_id = FMIC_CONN_MEM_LOW_ID | 3. A direct register does not need an offset and can be used as is. The possible register/memory IDs are defined as follows.

  - FMIC_MASTER_REG_ID selects the master control/status register (direct).
  - FMIC_CNTRL_REG_ID selects the FMIC control registers (indirect).
  - FMIC_DATA_MEMORY_ID selects the data memory (indirect).
  - FMIC_CONN_MEM_LOW_ID selects the low byte of the connection memory (indirect).
  - FMIC_CONN_MEM_HIGH_ID selects the high byte of the connection memory (indirect).

- Value indicates what should be written to the indicated register.

- Mask specifies the bits that the write will affect. Zero valued bits in the mask will not affect corresponding bits in the register/memory location.

**Return Value**

The function returns one of the following values:

- **OK**  Operation succeeded
- **ERROR**  Operation failed
Example

The following example sets the RESET bit in the master Control/Status register of FMIC device dev0 without affecting any other bits.

```c
int status;

status = fmic_write(dev0, FMIC_MASTER_REG_ID, 0x1, 0x1);
if (status == ERROR)
    return(ERROR);
```
2.5 Board Support Library API

This section discusses the McEVM board support library API. Included in this discussion are the functions defined that comprise the board library for the 'C62x McEVM board. No public macros are defined for this module.

The following alphabetical listing includes all of the board support library API functions. Use this listing as a table of contents to the board support library API functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpu_freq</td>
<td>Return current CPU frequency in MHz</td>

</tbody>
</table>
**cpu_freq**  
*Return Current CPU Frequency in MHz*

**Syntax**
```c
#include <board.h>
int cpu_freq( void );
```

**Defined in**
board.c as a callable C routine

**Description**
The `cpu_freq()` function determines the internal CPU clock frequency by reading the CLKMODE and CLKSEL bits in the DSPOPT register of the onboard complex programmable logic device (CPLD).

**Return Value**
CPU frequency in Mhz

---

**delay_msec**  
*Delay CPU for Indicated Number of Milliseconds*

**Syntax**
```c
#include <board.h>
int delay_msec( unsigned short numMsec );
```

**Defined in**
board.c as a callable C routine

**Description**
The `delay_msec()` function uses an available timer to delay the specified number of milliseconds before returning to the caller.

- The `numMsec` parameter is a value between 0 and 65 535. For delay values less than 1 ms, use the `delay_usec()` function.

**Return Value**
The function returns one of the following values:
- OK: Operation succeeded
- ERROR: Operation failed

---

**delay_usec**  
*Delay CPU for Indicated Number of Microseconds*

**Syntax**
```c
#include <board.h>
int delay_usec( unsigned short numUsec );
```

**Defined in**
board.c as a callable C routine

**Description**
The `delay_usec()` function uses an available timer to delay the specified number of microseconds before returning to the caller.

- The `numUsec` parameter is a value between 0 and 65 535. For delay intervals greater than 65.5 milliseconds, use the `delay_msec()` function.

**Return Value**
The function returns one of the following values:
- OK: Operation succeeded
- ERROR: Operation failed
**evm_codec_disable**  
Disconnect codec from 'C62x McBSP

**Syntax**  
#include (board.h>
int evm_codec_disable( void );

**Defined in**  
board.c as a callable C routine

**Description**  
The evm_codec_disable() function disconnects the codec from the 'C62x McBSP0 serial port.

**Return Value**  
The function returns one of the following values:
- OK Operation succeeded
- ERROR Operation failed

**evm_codec_enable**  
Connect codec to 'C62x McBSP

**Syntax**  
#include (board.h>
int evm_codec_enable( void );

**Defined in**  
board.c as a callable C routine

**Description**  
The evm_codec_enable() function disconnects the codec from the 'C62x McBSP0 serial port.

**Return Value**  
The function returns one of the following values:
- OK Operation succeeded
- ERROR Operation failed

**evm_default_emif_init**  
Initialize EMIF for McEVM Board to Default Parameters

**Syntax**  
#include <board.h>
void evm_default_emif_init( void );

**Defined in**  
board.c as a callable C routine

**Description**  
The evm_default_emif_init() function initializes the EMIF to default values that will work at any available CPU frequency.

**Return Value**  
None
**evm_emif_init**

*Initialize EMIF for McEVM Board*

**Syntax**

```c
#include <board.h>
void evm_emif_init( void );
```

**Defined in**

board.c as a callable C routine

**Description**

The `evm_emif_init()` function initializes the EMIF to clock rate-tailored values.

**Return Value**

None

---

**evm_init**

*Initialize McEVM Board*

**Syntax**

```c
#include <board.h>
int evm_init( void );
```

**Defined in**

board.c as a callable C routine

**Description**

The `evm_init()` function initializes the McEVM board for use by configuring base address variables based upon the 'C62x memory map (MAP 0 or MAP 1) and endian mode selected, initializing the EMIF and enabling the NMI bit in the interrupt enable register. This function must be called before any other DSP support software routines.

**Return Value**

The function returns one of the following values:

- **OK**: Operation succeeded
- **ERROR**: Operation failed

**Example**

This example initializes the McEVM board for use.

```c
int status;
status = evm_init( );
if (status == ERROR)
    return(ERROR);
```
### evm_led_disable

**Disable Selected McEVM LED**

**Syntax**

```c
#include <board.h>
int evm_led_disable( int ledNumber );
```

**Defined in**

board.c as a callable C routine

**Description**

The `evm_led_disable()` function extinguishes the selected LED on the McEVM board.

- Parameter `ledNumber` selects the LED to extinguish. Valid values are 0 (for LED0) or 1 (for LED1).

**Return Value**

The function returns one of the following values:

- **OK** Operation succeeded
- **ERROR** Operation failed

---

### evm_led_enable

**Enable Selected McEVM LED**

**Syntax**

```c
#include <board.h>
int evm_led_enable( int ledNumber );
```

**Defined in**

board.c as a callable C routine

**Description**

The `evm_led_enable()` function illuminates the selected LED on the McEVM board.

- The `ledNumber` parameter selects the LED to illuminate. Valid values are 0 (for LED0) or 1 (for LED1).

**Return Value**

The function returns one of the following values:

- **OK** Operation succeeded
- **ERROR** Operation failed
evm_nmi_disable

**Externally Disable NMI**

**Syntax**
```c
#include <board.h>
void evm_nmi_disable(void);
```

**Defined in**
board.c as a callable C routine

**Description**
The `evm_nmi_disable()` function externally disables the NMI source to the 'C62x by clearing the NMIEN bit in the CNTL register of the McEVM CPLD.

**Return Value**
None

---

evm_nmi_enable

**Externally Enable NMI**

**Syntax**
```c
#include <board.h>
void evm_nmi_enable(void);
```

**Defined in**
board.c as a callable C routine

**Description**
The `evm_nmi_enable()` function externally enables the NMI source to the 'C62x by setting the NMIEN bit in the CNTL register of the McEVM CPLD.

**Return Value**
None

---

evm_nmi_sel

**Select the Source for NMI**

**Syntax**
```c
#include <board.h>
void evm_nmi_sel(int sel);
```

**Defined in**
board.c as a callable C routine

**Description**
The `evm_nmi_sel()` function selects the source for NMI to the 'C62x by setting or clearing the NMISEL bit in the CNTL register of the McEVM CPLD. Parameter `sel` selects the host (0) or the codec (1) as the NMI source.

**Return Value**
None
2.6 T1/E1 Framer Driver Library

The Siemens PEB 2255 T1/E1 Framer and Line Interface supports a single channel bi-directional T1/E1 connection and a single bi-directional 2Mbit serial stream. The interface presented is specific to the use of this chip on the McEvum and potential daughterboard.

2.6.1 T1/E1 API Data Structures and ENUMs

```c
typedef struct{   FALC_REG_MAP* pxReg; /* Pointer to FALC registers */
    unsigned char* pu8RcData; /* Current receive data pointer */
    unsigned char* pu8TxData; /* Current transmit data pointer */
    unsigned short u16TxCnt; /* Transmit byte counter */
    falc_pcm_mode pcmMode; /* 0: PCM 30 mode, 1: PCM 24 mode */
    int l1State; /* Layer 1 state */
    unsigned char dummy [4]; /* Forces size of data structure to */
    /* 2^n, which guarantees SHLn */
    /* operations instead of IMUL for a */
    /* access to structure elements */
} FALC_DEVICE_CTRL;

typedef struct{ t1e1_state state; unsigned int base_addr; FALCDEVICE_CTRL falc;}T1E1_DEV;

typedef enum{  PCM_30_MODE = 0x00,

2.6.2 Siemens PEB 2255 T1/E1 Framer and Line Interface Registers

Register information is given in Siemens PEB 2255 data sheet T2255-XV11-P1-7600.

2.6.3 T1/E1 API Functions

This section includes the library T1/E1 Framer Driver API functions for the C6x McEVM. The following is an alphabetical listing of these API functions which can be used as a table of contents.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1e1_channel_loopback</td>
<td>Enable or disable channel loopback for a specified channel.</td>
<td>2-48</td>
</tr>
<tr>
<td>t1e1_close</td>
<td>De-initialize the software driver for the T1/E1 device.</td>
<td>2-49</td>
</tr>
<tr>
<td>t1e1_configure</td>
<td>Register initialization from a configuration array of registers and values.</td>
<td>2-49</td>
</tr>
<tr>
<td>t1e1_framing</td>
<td>Set the Framing Mode register.</td>
<td>2-50</td>
</tr>
<tr>
<td>t1e1_init</td>
<td>Initialize the T1/E1 framer to specified values.</td>
<td>2-50</td>
</tr>
<tr>
<td>t1e1_install</td>
<td>Install a callback function to handle interrupts.</td>
<td>2-51</td>
</tr>
<tr>

<tr>
<td>t1e1_loopback</td>
<td>Enable or disable Payload, Remote, and/or Local Loopbacks.</td>
<td>2-52</td>
</tr>
<tr>
<td>t1e1_open</td>
<td>Initialize the software driver for the T1/E1 device.</td>
<td>2-53</td>
</tr>
<tr>
<td>t1e1_read</td>
<td>Read the specified T1/E1 register.</td>
<td>2-53</td>
</tr>
<tr>
<td>t1e1_reset</td>
<td>Reset all register values to power on states.</td>
<td>2-54</td>
</tr>
<tr>
<td>t1e1_sync</td>
<td>Set the sync timing mode for the T1/E1 Framer.</td>
<td>2-54</td>
</tr>
<tr>
<td>t1e1_write</td>
<td>Write to the specified T1/E1 register.</td>
<td>2-55</td>
</tr>
</tbody>
</table>
t1e1_channel_loopback

Enables or Disables Loopback for Specified Channel

Syntax

```c
#include<t1e1.h>
int t1e1_channel_loopback(
    T1E1_DEV_T dev,
    unsigned int channel,
    unsigned int channel_loopback_enable,
    unsigned int idle_code)
```

Defined in
t1e1.c as a callable C routine

Description

The `t1e1_channel_loopback` function either enables or disables loopback for a specified channel.

- The `t1e1_dev` parameter refers to the initialized device handle returned by `t1e1_open`.
- The `channel` parameter specifies the channel to loopback.
- The `channel_loopback_enable` parameter values are 1=enable, 0=disable.
- The `idle_code` is the value for idle code insertion.

Return Value

The function returns one of the following values:

- **OK**: Operation succeeded
- **ERROR**: Operation failed
**t1e1_close**

*De-initializes the Software Driver*

**Syntax**  
```c  
#include "t1e1.h"  
int t1e1_close(  
    T1E1_DEV_T  dev)  
```

**Defined in**  
`t1e1.c` as a callable C routine

**Description**  
The `t1e1_close` function invalidates the T1/E1 device handle.

- The parameter `t1e1_dev` refers to the initialized device handle returned by `t1e1_open`.

**Return Value**  
The function returns one of the following values:

- OK Operation succeeded
- ERROR Operation failed

---

**t1e1_configure**

*Allows Register Initialization*

**Syntax**  
```c  
#include "t1e1.h"  
int t1e1_configure(  
    T1E1_DEV_T  t1e1dev,  
    t1e1_configuration  t1e1_configuration)  
```

**Defined in**  
`t1e1.c` as a callable C routine

**Description**  
This function allows register initialization via a configuration array.

- The `t1e1_dev` parameter refers to the initialized device handle returned by `t1e1_open`.

- The `t1e1_configuration` parameter is an array of tuples of the form (unsigned int register_id, unsigned int value, unsigned int mask) and is terminated by an entry with a mask of 0.

**Return Value**  
The function returns one of the following values:

- OK Operation succeeded
- ERROR Operation failed
t1e1_framing

Sets the Framing Mode Register

Syntax

```c
#include<t1e1.h>

int t1e1_framing(
    T1E1_DEV_T t1e1_dev,
    unsigned int frame_mode)
```

Defined in t1e1.c as a callable C routine

Description

Sets the framing mode register according to value specified in frame_mode.

- The t1e1_dev parameter refers to the initialized device handle returned by t1e1_open.
- For a description of the frame_mode parameter see t1e1_framing_mode enum list.

Return Value

The function returns one of the following values:

- OK     Operation succeeded
- ERROR  Operation failed

---

t1e1_init

Initializes the T1/E1 Framer to Specified Values

Syntax

```c
#include<t1e1.h>

int t1e1_init(
    T1E1_DEV_T t1e1_dev,
    unsigned int line_mode,
    unsigned int line_code_mode,
    unsigned int framing_mode,
    unsigned int sync_mode,
    unsigned int loopback_mode)
```

Defined in t1e1.c

Description

Establish normal operating register values for the T1/E1 Framer. These include setting line mode (T1 or E1), line code mode (AMI and B8ZS or AMI and HDB3), framing mode (D4, ESF | CRC_4_MULTIFRAME, DOUBLE_FRAME), sync mode (loop, FMIC | loop, FMIC), and loopback mode(s) (none, local, payload, remote, local and remote).

- The t1e1_dev parameter refers to the initialized device handle returned by t1e1_open.
For a description of the `line_mode` parameter see `t1e1_line_mode` enum list.

For a description of the `line_code_mode` parameter see `t1e1_line_code_mode` enum list.

For a description of the `framing_mode` parameter see `t1e1_framing_mode` enum list.

For a description of the `sync_mode` parameter see `t1e1_sync_mode` enum list.

For a description of the `loopback_mode` parameter see `t1e1_loopback_mode` enum list.

**Return Value**

The function returns one of the following values:

- **OK** Operation succeeded
- **ERROR** Operation failed

---

**t1e1_install**

Installs a Callback Function to Handle Interrupts

**Syntax**

```c
#include <t1e1.h>

int t1e1_install(
    T1E1_DEV_T   t1e1_dev,
    unsigned int register_id,
    unsigned int mask,
    T1E1_CALLBACK_T *pf_ract)
```

**Defined in**

t1e1.c as a callable C routine

**Description**

The parameters are as follows:

- The `t1e1_dev` parameter refers to the initialized device handle returned by `t1e1_open`.
- The `register_id` parameter refers to the interrupt mask register (0x14-0x19).
- The `mask` parameter refers to the interrupt mask (bit = 1 sets interrupt active).
- The `*pf_ract` parameter refers to the function which interrupt service routines will call.

**Return Value**

The function returns one of the following values:

- **OK** Operation succeeded
- **ERROR** Operation failed
**t1e1_linecode**

Sets the RX and TX Line Code Registers

**Syntax**

```c
#include <t1e1.h>
int t1e1_linecode(
    T1E1_DEV_T t1e1_dev,
    unsigned int line_code_mode)
```

**Defined in**

`t1e1.c` as a callable C routine

**Description**

The `t1e1_linecode` function sets the RX and Tx Line Code Registers.

- The `t1e1_dev` parameter refers to the initialized device handle returned by `t1e1_open`.
- For a description of the `line_code_mode` parameter see `t1e1_line_code_mode` enum list.

**Return Value**

The function returns one of the following values:

- OK: Operation succeeded
- ERROR: Operation failed

---

**t1e1_loopback**

Enables or Disables Payload, Remote, and/or Local Loopback(s)

**Syntax**

```c
#include <t1e1.h>
int t1e1_loopback(
    T1E1_DEV_T t1e1_dev,
    unsigned int loopback_mode)
```

**Defined in**

`t1e1.c` as a callable C routine

**Description**

The `t1e1_loopback` function enables or disables the specified loopback.

- The `t1e1_dev` parameter refers to the initialized device handle returned by `t1e1_open`.
- For a description of the `loopback_mode` parameter, see `t1e1_loopback_mode` enum list. (T1E1_NO_LOOPBACK to disable).

**Return Value**

The function returns one of the following values:

- OK: Operation succeeded
- ERROR: Operation failed
**t1e1_open**

Initializes the Software Driver

Syntax

```
#include <t1e1.h>
T1E1_DEV_T t1e1_open(
    unsigned int t1e1_base_address)
```

Defined in

t1e1.c as a callable C routine

Description

Provides a handle to reference a T1/E1 device.

- The parameter `t1e1_base_address` is the base address of the T1/E1 device.

Return Value

The function returns one of the following values:

- **OK** Operation succeeded
- **ERROR** Operation failed

---

**t1e1_read**

Returns the Value Contained in the Indicated Register

Syntax

```
#include <t1e1.h>
unsigned int t1e1_read(
    T1E1_DEV_T t1e1_dev,
    unsigned int register_id)
```

Defined in

t1e1.c as a callable C routine

Description

The `t1e1_read` function reads the specified register.

- The `t1e1_dev` parameter refers to the initialized device handle returned by `t1e1_open`.
- The `register_id` parameter refers to the register number.

Return Value

Value of specified register.
**t1e1_reset**

*Resets All Register Values to Power-Up States*

**Syntax**

```c
#include<t1e1.h>
int t1e1_reset(
    T1E1_DEV_T t1e1_dev)
```

**Defined in**

`t1e1.c` as a callable C routine

**Description**

Reset all registers values to power up status.

- The parameter `t1e1_dev` refers to the initialized device handle returned by `t1e1_open`.

**Return Value**

The function returns one of the following values:

- **OK** Operation succeeded
- **ERROR** Operation failed

---

**t1e1_sync**

*Sets the Sync Timing Mode for the T1/E1 Framer*

**Syntax**

```c
#include<t1e1.h>
int t1e1_sync(
    T1E1_DEV_T t1e1_dev,
    unsigned int sync_mode)
```

**Defined in**

`t1e1.c` as a callable C routine

**Description**

Set the sync timing mode for the T1/E1 Framer.

- The `t1e1_dev` parameter refers to the initialized device handle returned by `t1e1_open`.
- For a description of the `sync_mode` parameter see `t1e1_sync_mode` enum list.

**Return Value**

The function returns one of the following values:

- **OK** Operation succeeded
- **ERROR** Operation failed
t1e1_write

Writes to the specified T1/E1 Register

Syntax

```c
#include <t1e1.h>

int t1e1_write(
    T1E1_DEV_T t1e1_dev,
    unsigned int register_id,
    unsigned int value,
    unsigned int mask)
```

Defined in t1e1.c as a callable C routine

Description

Write a value into a register, limit the bits written to those which are set in mask.

Return Value

The function returns one of the following values:

- **OK**: Operation succeeded
- **ERROR**: Operation failed
2.7 VBAP Driver Library API

The TCM320AC36/7 voice-band audio processor (VBAP) integrated circuits are designed to perform the transmit and receive encoding and decoding (A/D and D/A conversions) together with transmit and receive filtering for voice-band communications systems. The interface presented is specific to the use of this chip on the McEVM.

2.7.1 VBAP API ENUMs

typedef enum { VBAP_A_LAW=0, VBAP_U_LAW} vbap_law;

2.7.2 VBAP Library API Functions

The following alphabetical listing includes all of the VBAP library API functions. Use this listing as a table of contents to the VBAP library API functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>vbap_set</td>
<td>Sets the specified companding type for A/D and D/A conversions.</td>
<td>2-57</td>
</tr>
<tr>
<td>vbap_get</td>
<td>Returns the current companding type for A/D and D/A conversions.</td>
<td>2-57</td>
</tr>
</tbody>
</table>
vbap_set

Sets the Companding type for A/D and D/A Conversions

Syntax

#include<vbap.h>
int vbap_set(vbap_law law);

Defined in
In vbap.c as a callable C routine

Description
Sets the companding type to that specified (A-law or µ-law). See vbap_law enum list for parameter law.

Return Value
Returns OK

vbap_get

Gets the Current Companding Type for A/D and D/A Conversions

Syntax

#include<vbap.h>
vbap_law vbap_get(void);

Defined in
In vbap.c as a callable C routine

Description
Gets the current companding type.

Return Value
Returns current companding selection.(See vbap_law enum list).OK
2.8 PCI/AMCC Driver Library API

This section discusses the PCI/AMCC library API. Included in this discussion are the macros, data types, and defined functions that comprise the PCI/AMCC library for the ‘C62x McEVM board.

2.8.1 PCI/AMCC Library Data Types and Macros

/* function typedefs for callback functions*/
typedef void pci_fifo_callback( int status );
typedef void pci_msg_callback( int status );

2.8.2 PCI/AMCC Library API Functions

The following alphabetical listing includes all of the PCI/AMCC library API functions. Use this listing as a table of contents to the PCI/AMCC library API functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>pci_driver_int(void)</td>
<td>Initializes the PCI Driver</td>
<td>2-59</td>
</tr>
<tr>
<td>pci_fifo_open</td>
<td>Opens the driver for the PCI FIFO device</td>
<td>2-60</td>
</tr>
<tr>
<td>pci_fifo_close</td>
<td>Closes the driver for the PCI FIFO device</td>
<td>2-61</td>
</tr>
<tr>
<td>pci_fifo_async_send</td>
<td>Starts an asynchronous PCI FIFO send operation</td>
<td>2-62</td>
</tr>
<tr>
<td>pci_fifo_sync_send</td>
<td>Starts a synchronous PCI FIFO send operation</td>
<td>2-63</td>

</tr>
<tr>
<td>amcc_mailbox_read</td>
<td>Reads a AMCC mailbox</td>
<td>2-74</td>
</tr>
<tr>
<td>amcc_mailbox_write</td>
<td>Writes to a AMCC mailbox</td>
<td>2-75</td>
</tr>
</tbody>
</table>
pci_driver_init(void)

*Initializes the PCI Driver*

**Syntax**
```
#include <pci.h>
void pci_driver_init( void )
```

**Defined in**
pci.c as a callable C routine

**Description**
This routine initializes the software driver if it has not been initialized previously. This includes setting up the messaging and the PCI FIFO transfer portions of the driver. Note that this function must be called before using any of the driver calls. But, also note that this function is called as part of the pci_fifo_open() function. So, if the pci_fifo_open() call is the first use of this driver, the pci_driver_init() is not required.

Also, the messaging calls in this driver use the mailbox 1 register of the AMCC PCI controller in both directions. Thus, this mailbox is not available for direct accesses using the mailbox read and write routines.

**Return Value**
None

**Example**
```
#include <board.h>
#include <pci.h>

main()
{
    evm_init();
    pci_driver_init();
    ...
}
```
PCI FIFO Open

Opens the Driver for the PCI FIFO Device

Syntax

```
#include <pci.h>
int pci_fifo_open( void )
```

Defined in
pci.c as a callable C routine

Description

This routine opens and initializes the PCI FIFO device used to communicate with the host.

Return Value

return a channel number to reference the device or an 'invalid' channel number if the device is already open (an invalid channel number is anything less than 0)

Example

```c
#include <board.h>
#include <pci.h>
...

int pci_chan;

evm_init();
pci_chan = pci_fifo_open();

if (pci_chan < 0)
{
    /* pci_fifo_open() failed */
}
...
```
pci_fifo_close

Closes the Driver for the PCI FIFO Device

Syntax

```c
#include <pci.h>
int pci_fifo_close( int chan )
```

Defined in

pci.c as a callable C routine

Description

This routine closes the PCI FIFO device.

- The chan parameter is the channel number returned from a successful open.

Return Value

Returns OK or ERROR; possible error conditions include: device not open

Example

```c
#include <board.h>
#include <pci.h>
.
.
.

int  pci_chan;

  evm_init();
  pci_chan = pci_fifo_open();

  pci_fifo_close( pci_chan );

  .

  .
```
pci_fifo_async_send

Starts an Asynchronous PCI FIFO Send Operation

Syntax

```c
#include <pci.h>

int pci_fifo_async_send(int chan, unsigned int *p_buffer, unsigned int num_bytes, pci_host_callback *p_callback);
```

Defined in
pci.c as a callable C routine

Description

This routine starts a data transfer to the host using DMA. It returns immediately, then the callback function is executed when the operation has completed. Note that each individual bus transaction is 32bits in size so num_bytes must be a multiple of four and p_buffer must be 32bit aligned. If a close is called during a pending async operation, the operation is aborted and the callback is called with an error status. Also, only one FIFO send operation is supported at a time, but it can be concurrent with a FIFO receive operation.

- The chan parameter is the channel number from a successful open.
- The p_buffer parameter is the location of the data to be written to the FIFO. This address must be 32-bit aligned.
- The num_bytes parameter is the number of bytes of data to be written to the FIFO. This number must be a multiple of 4.
- The p_callback parameter is the function pointer for the callback routine.

Return Value

OK or ERROR

Possible error conditions include: another send in progress, chan not open, no DMA chan available.

Example

```c
#include <board.h>
#include <pci.h>
...

int pci_chan;
evm_init();
pci_chan = pci_fifo_open();
...
```
PCI FIFO Synchronous Send Operation

**Use Case**: Starts a Synchronous PCI FIFO Send Operation

**Syntax**

```c
#include <pci.h>

int pci_fifo_sync_send(
    int chan,
    unsigned int * p_buffer,
    unsigned int num_bytes
)
```

**Defined in**

pci.c as a callable C routine

**Description**

This routine sends data to the PCI FIFO. It will return when the transfer is complete. This function does not use DMA; it polls the FIFO flags and writes data to the FIFO directly.

- The `chan` parameter is the channel number from a successful open.
- The `p_buffer` parameter is the location of the data to be written to the FIFO. This address must be 32 bit aligned.
- The `num_bytes` parameter is the number of bytes of data to be written to the FIFO. This number must be a multiple of 4.

**Return Value**

OK or ERROR

Possible error conditions include: chan not open, another send in progress.

**Example**

```c
#include <board.h>
#include <pci.h>

unsigned int buffer[0x48];
...

int pci_chan;

evm_init();

pci_chan = pci_fifo_open();

pci_fifo_sync_send( pci_chan, buffer, 0x48*4 );
...
```
**pci_fifo_async_receive**

**Starts an Asynchronous PCI FIFO Receive Operation**

**Syntax**

```c
#include <pci.h>
int pci_fifo_async_receive(
    int chan,
    unsigned int * p_buffer,
    unsigned int num_bytes,
    pci_host_callback * p_callback)
```

**Defined in**

pci.c as a callable C routine

**Description**

This routine begins an asynchronous FIFO receive operation using DMA. It returns immediately and the callback function is called when the operation completes. Note that each individual bus transaction is 32 bits in size so `num_bytes` must be a multiple of four and `p_buffer` must be 32bit aligned. If a close is called during a pending async operation, the operation is aborted and the callback is called with an error status. Also, only one FIFO receive operation is supported at a time, but it can be concurrent with a FIFO send operation.

- The `chan` parameter is the channel number from a successful open.
- The `p_buffer` parameter is the location of the data to be written to the FIFO. This address must be 32-bit aligned.
- The `num_bytes` parameter is the number of bytes of data to be written to the FIFO. This number must be a multiple of 4.
- The `p_callback` parameter is the function pointer for the callback routine.

**Return Value**

OK or ERROR.

Possible error conditions include: chan not open, another receive in progress, no DMA chan available.

**Example**

```c
#include <board.h>
#include <pci.h>
.
.
    int pci_chan;
    evm_init();
    pci_chan = pci_fifo_open();
.
.
```
Starts a Synchronous PCI FIFO Receive Operation

Syntax

```c
#include <pci.h>

int pci_fifo_sync_receive(
    int chan,
    unsigned int * p_buffer,
    unsigned int num_bytes)
```

Defined in

defined in pci.c as a callable C routine

Description

This routine receives data from the PCI FIFO. It will return when the transfer is complete. This function does not use DMA; it polls the FIFO flags and reads data from the FIFO directly.

- The chan parameter is the channel number from a successful open.
- The p_buffer parameter is the location of the data to be written to the FIFO. This address must be 32 bit aligned.
- The num_bytes parameter is the number of bytes of data to be written to the FIFO. This number must be a multiple of 4.

Return Value

OK or ERROR

Possible error conditions include: chan not open, another receive in progress.

Example

```c
#include <board.h>
#include <pci.h>

unsigned int buffer[72];
...

int pci_chan;

evm_init();

pci_chan = pci_fifo_open();

pci_fifo_sync_receive( pci_chan, buffer, 72<<2 );
...
```
pci_message_send

Sends a Message Immediately

Syntax

```
#include <pci.h>
int pci_message_send( unsigned int message )
```

Defined in

pci.c as a callable C routine

Description

This routine sends a 32-bit message. If the message cannot be placed into the mailbox immediately, it returns with an error and the message is not sent. This routine checks mailbox empty/full flags and the HINT bit. If outgoing mailbox 1 is empty and HINT is clear, it places message into mailbox 1. It then sets the HINT bit to cause an interrupt to the host.

- The message parameter is the 32-bit value to be sent to the host.

Return Value

OK or ERROR

Possible error conditions include: outgoing message mailbox not empty, HINT not clear.

Example

```
#include <board.h>
#include <pci.h>
.
.
evm_init();
pci_driver_init();
.
.
if ( pci_message_send( 0x1234fedc ) != OK )
{
    /* message send failed */
}
.
.
```
**pci_message_async_send**

Starts an Asynchronous Message Operation

**Syntax**

```
#include <pci.h>

int pci_message_async_send(
    unsigned int message,
    bool wait_for_ack,
    pci_message_callback * p_callback
)
```

**Defined in**

pci.c as a callable C routine

**Description**

This routine will begin a send message operation. The call will return immediately. The callback will be called when the operation is complete. This routine uses interrupts internally; it does not poll. If wait_for_ack is TRUE, then callback is not called until the message has been read by the host. If it is FALSE then callback is called as soon as the message is placed into the outgoing mailbox.

- The message parameter is the 32-bit value to be sent to the host.
- The wait_for_ack parameter determines when the operation is considered complete and the callback function is called.
- The p_callback parameter is the function pointer for the callback routine.

**Return Value**

OK or ERROR

Possible error conditions include: another send in progress.

**Example**

```
#include <board.h>
#include <pci.h>

. . .

int pci_chan;

evm_init();
pci_chan = pci_fifo_open();

. . .
```
prar message sync send

#include <pci.h>

    ... 
    int pci_chan;
    
    evm_init();
    pci_driver_init();
    /* send message, return when message is read by host */
    pci_message_sync_send( 0x00223300, TRUE );
    
    ... 
```
**pci_message_retrieve**

*Retrieves a Message Immediately*

**Syntax**

```
#include <pci.h>
int pci_message_retrieve( unsigned int *p_message )
```

**Defined in**

`pci.c` as a callable C routine

**Description**

This routine retrieves a message sent by the host. If there is no message available, it returns ERROR. This function checks mailbox empty/full flags; if mailbox 1 is full, the message is read from the mailbox 1 register.

- The `p_message` parameter is the location to store the 32-bit value retrieved from the host.

**Return Value**

OK or ERROR

Possible error conditions include: incoming message mailbox not full.

**Example**

```
#include <board.h>
#include <pci.h>
.
.
unsigned int *p_message;

evm_init();
pci_driver_init();
if ( pci_message_retrieve( p_message ) != OK )
{
    /* no message available */
}
.
.
```
**pci_message_async_retrieve**

*Starts an Asynchronous Retrieve Message Operation*

**Syntax**

```c
#include <pci.h>

int pci_message_async_retrieve(
    unsigned int *p_message,
    pci_message_callback *p_callback)
```

**Defined in**

pci.c as a callable C routine

**Description**

This routine begins an asynchronous message retrieve operation. It returns immediately. When the operation is complete, the callback function is called. This function uses interrupts internally; it does not poll.

- The `p_message` parameter is the location to store the 32-bit value retrieved from the host.
- The `p_callback` parameter is the function pointer for the callback routine.

**Return Value**

OK or ERROR

Possible error conditions include: another retrieve in progress.

**Example**

```c
#include <board.h>
#include <pci.h>
...
    unsigned int *p_message;

    evm_init();
    pci_driver_init();
...
```
Starts a Synchronous Retrieve Message Operation

**Syntax**

```c
#include <pci.h>

int pci_message_sync_retrieve( unsigned int *p_message )
```

**Defined in**

`pci.c` as a callable C routine

**Description**

This routine will retrieve a 32-bit message sent by the host. It will not return until the operation is complete. This function is implemented by calling `pci_message_async_retrieve()` and waiting internally for the operation to complete.

- The `p_message` parameter is the location to store the 32-bit value retrieved from the host.

**Return Value**

returns OK or ERROR, possible error conditions include: another retrieve in progress.

**Example**

```c
#include <board.h>
#include <pci.h>

... 

unsigned int  *p_message;

evm_init();
pci_driver_init();
pci_message_sync_retrieve( p_message );
       /* retrieved message in *p_message */
...
```
amcc_nvram_read

Reads a Byte from NVRAM

Syntax

```
#include <pci.h>

int amcc_nvram_read(
    unsigned short offset,
    unsigned char * p_data
)
```

Defined in

pci.c as a callable C routine

Description

This routine returns the byte of data at the indicated offset to the p_data address. Note that the NVRAM device on the EVM and McEVM boards is 2K bytes in size.

- The offset parameter is the address offset into the NVRAM device.
- The p_data parameter is the location to store the 8-bit value read from NVRAM.

Return Value

OK or ERROR

Possible error conditions include: offset out of range.

Example

```
#include <board.h>
#include <pci.h>
...

    unsigned char uc_data;

    evm_init();
    pci_driver_init();
    amcc_nvram_read( 0x01e8, &uc_data );
... 
```
**Syntax**

```c
#include <pci.h>

int amcc_nvram_write(
    unsigned short offset,
    unsigned char data
)
```

**Defined in**

pci.c as a callable C routine

**Description**

This routine will write the byte of data to NVRAM at the indicated offset. This routine will not allow the modification of data between offsets of 0x0000 and 0x007f. Offsets 0x0000 through 0x007f are used for PCI configuration and should not be modified.

- The offset parameter is the address offset into the NVRAM device.
- The data parameter is the 8-bit value to write to NVRAM.

**Return Value**

OK or ERROR, possible error conditions include: invalid offset, offset out of range.

**Example**

```c
#include <board.h>
#include <pci.h>

. . .

    unsigned char           uc_data;

    evm_init();
    uc_data = 0x4e;

    pci_driver_init();
    amcc_nvram_write( 0x02f0, uc_data );

. . .
```
Reads a AMCC Mailbox

Syntax

```c
#include <pci.h>
int amcc_mailbox_read(
    int mailbox_number,
    unsigned int * p_data )
```

Defined in

pci.c as a callable C routine

Description

This routine will read the contents of one of the mailbox registers not used by the pci_message_xxx() calls. If the indicated mailbox is not full this routine will return ERROR. Note that mailbox register 1 is used for the pci_message_xxx() calls so it is not available to this routine.

- The mailbox_number parameter is the mailbox register number to be checked. It must be a value of 2, 3 or 4.
- The p_data parameter is the location to store the 32-bit value sent by the host.

Return Value

OK or ERROR

Possible error conditions include: invalid mailbox number (must be 2, 3 or 4), mailbox not full.

Example

```c
#include <board.h>
#include <pci.h>
.
.
    unsigned int  data;

    evm_init();
    pci_driver_init();
    amcc_mailbox_read( 2, &data );
    
.
.
```
amcc_mailbox_write

Writes to an AMCC Mailbox

**Syntax**

```c
#include <pci.h>
int amcc_mailbox_write(
    int mailbox_number,
    unsigned int data
)
```

**Defined in**

pci.c as a callable C routine

**Description**

This routine will place a 32-bit word into one of the mailbox registers not used by the pci_message_xxx() calls. If the indicated mailbox is not empty, this routine will return ERROR. Mailbox register 1 is used for the pci_message_xxx() calls so it is not available to this routine.

Note that byte 3 of outgoing mailbox register 4 is not writeable so writing to this byte will have no effect. On the host side, byte 3 of incoming mailbox register 4 contains hardware signal information (see the EVM reference guide for details).

- The mailbox_number parameter is the mailbox register number to be checked. It must be a value of 2, 3 or 4.
- The data parameter is the 32bit value to be sent to the host.

**Return Value**

OK or ERROR, possible error conditions include: invalid mailbox number (must be 2, 3 or 4), mailbox not empty

**Example**

```c
#include <board.h>
#include <pci.h>
.
.
evm_init();
pci_driver_init();
amcc_nvram_write( 3, 0x9876abcd );
.
.
```
2.9 C I/O Interface Library API

This section discusses the C I/O Interface library API. Included in this discussion are the macros, data types, and defined functions that comprise the C I/O Interface library for the 'C62x McEVM board.

The following alphabetical listing includes all of the C I/O Interface library API functions. Use this listing as a table of contents to the C I/O Interface library API functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Page</th>

<td>2-80</td>
</tr>
<tr>
<td>cio_pci_fifo_rename</td>
<td>Renames the file [not supported]</td>
<td>2-80</td>
</tr>
</tbody>
</table>
cio_pci_fifo_open

Opens the C I/O Interface to the AMCC/PCI Driver

Syntax

```c
#include <cio_fifo.h>

int cio_pci_fifo_open(
    const char *path,
    unsigned flags,
    int mode
)
```

Defined in
cio_fifo.c as a callable C routine

Description

This routine opens the FIFO channel to the host. Note that only one stream is supported and that this function utilizes the pci_fifo_open() routine.

- The path parameter is ignored.
- The mode parameter is ignored.
- The flags parameter specify how the device is manipulated.

Return Value

A stream number on success or <0 on failure

Example

```c
#include <board.h>
#include <stdio.h>
#include <cio_fifo.h>

unsigned int buffer[0x80];

main()
{
    FILE *fid;
    evm_init();
    add_device( "pci_fifo", _SSA,
        cio_pci_fifo_open,
        cio_pci_fifo_close,
        cio_pci_fifo_read,
        cio_pci_fifo_write,
        cio_pci_fifo_lseek,
        cio_pci_fifo_unlink,
        cio_pci_fifo_rename );

    fid = fopen( "pci_fifo:", "rw" );
```
cic_pci_fifo_read

/* read from host using pci_fifo device */
fwrite( buffer, 4, 0x80, fid);

/* write to host using pci_fifo device */
fwrite( buffer, 4, 0x80, fid);
fclose( fid);

cic_pci_fifo_read

Reads the C I/O Interface to the AMCC/PCI Driver

Syntax

#include <cio_fifo.h>

Syntax

int cic_pci_fifo_read(
    int fildes,
    char *bufptr,
    unsigned cnt)

Defined in
cio_fifo.c as a callable C routine

Description

This function reads the number of characters indicated by 'cnt' from the pci_fifo device.

- The fildes parameter is the stream number returned from a successful open call.
- The bufptr parameter is the location of the buffer where read data is placed.
- The cnt parameter is the number of characters to be read from the device.

Return Value

Returns the number of characters read or -1 on failure

Example

See the example for pci_fifo_open().
cio_pci_fifo_write

Writes to the Host Using the AMCC/PCI Driver

Syntax

```
#include <cio_fifo.h>

int cio_pci_fifo_write(
    int fildes,
    const char *bufptr,
    unsigned cnt)
```

Defined in
cio_fifo.c as a callable C routine

Description

This function writes the number of characters indicated by `cnt` to the pci_fifo device.

- The `fildes` parameter is the stream number returned from a successful open call.
- The `bufptr` parameter is the location of the buffer of data to be sent to the device.
- The `cnt` parameter is the number of characters to be sent to the device.

Return Value

Returns the number of characters written or -1 on failure.

Example

See the example for pci_fifo_open().

Sets the File Position Indicator

cio_pci_fifo_lseek

Syntax

```
#include <cio_fifo.h>

int cio_pci_fifo_lseek(
    int fildes,
    long offset,
    int origin)
```

Defined in
cio_fifo.c as a callable C routine

Description

This function is not supported by the pci_fifo device.

Return Value

Always returns E0F (lseek is not supported).
**cio_pci_fifo_close**

*Closes the C I/O Interface to the AMCC/PCI Driver*

**Syntax**

```
#include <cio_fifo.h>

int cio_pci_fifo_close(int fildes)
```

**Defined in**

cio_fifo.c as a callable C routine

**Description**

This function closes the pci_fifo device.

- The fildes parameter is the stream number returned from a successful open call.

**Return Value**

Returns 0 on success or -1 on failure.

**Example**

See the example for pci_fifo_open().

---

**cio_pci_fifo_unlink**

*Deletes the File*

**Syntax**

```
#include <cio_fifo.h>

int cio_pci_fifo_unlink(const char *path)
```

**Defined in**

cio_fifo.c as a callable C routine

**Description**

This function is not supported by the pci_fifo device.

**Return Value**

Always returns -1 (unlink is not supported).

---

**cio_pci_fifo_rename**

*Renames the File*

**Syntax**

```
#include <cio_fifo.h>

int cio_pci_fifo_rename(  
    const char *old_name,  
    const char *new_name)
```

**Defined in**

cio_fifo.c as a callable C routine

**Description**

This function is not supported by the pci_fifo device.

**Return Value**

Always returns -1 (rename is not supported).
This appendix contains the pinout information for each connector on the TMS320C62x McEVM.

A.8 CPLD ISP Header

Connector J7 provides the CPLD’s JTAG in-system programming port that allows the McEVM’s onboard logic to be reprogrammed. This connector is a 10-pin header (two rows of five pins) with connections shown in Table A–8 to communicate with the Altera ByteBlaster™ parallel port cable. The 10-pin female connector on the cable is connected to the male header on the McEVM. The pins have 0.025-inch square posts with 0.100-inch spacing.

The J7 CPLD ISP connector is for factory use and is not installed.

A.11 TMS320C62x JTAG Emulation Header

Connector J10 provides the 'C6201's emulation port based on the IEEE 1149.1 standard. This connector is a 14-pin header (two rows of seven pins) with connections shown in Table A–11 to communicate with an XDS510 emulator. Pin 6 is used for keying to ensure a proper connection.

C.1 Overview of the McEVM CPLD

The CPLD is an Altera EPM7256SQC208–10 device that has a 208-pin PQFP package. A summary of the pin allocation is shown in Table C–1.

Table C–1. TMS320C62x McEVM CPLD Pin Summary

</tbody>
</table>

The EPM7256SQC208–10 CPLD provides 5000 usable gates, of which approximately 75% are used in this design. The device contains 256 macro-cells arranged in 16 logic array blocks. The maximum pin-to-pin delay is 10.5 ns. The CPLD uses 5 V for internal operation and 3.3 V for its I/O buffers. It can interface to both 3.3- and 5-V devices.

The CPLD was designed using Synario™ ABEL™ version 6.5 and Altera MAX+ PLUS™ II version 8.1. Synario was used to enter the design in the ABEL hardware design language, and MAX+ PLUS II was used for design compilation, simulation, and programming file generation.

The CPLD’s VHD source files are modular with a top-level module and six low-level modules as shown in Figure C–1. These seven source files are provided in section C.2, *McEVM CPLD Equations*. 
Table C–2 and Table C–3 provide the CPLD pin definitions in numerical and sequential alphabetical order, respectively.

-- Design For:
-- Texas Instruments Incorporated

-- Design By:
-- DNA Enterprises Inc
-- 269 West Renner Parkway
-- Richardson, TX 75080

-- File name : mcevm_ctrl.vhd
-- Title : Top Level McEVM Control CPLD design
-- Module :
-- Description : This is the top-level module for the TMS320C6x McEVM's CPLD. This top level only contains
-- instantiations of the lower level components
-- and the concurrent statements to tri-state
-- outputs when required.

-- Modification History :

-- Revision: 0
-- Date: 03/30/98
-- Author: Don Curry (DNA)
-- Description: Initial conversion from ABEL version of EVM CPLD.
--
-- Revision: 1
-- Date: 05/05/98
-- Author: Don Curry (DNA)

-- Design For:
-- Texas Instruments Incorporated
--
-- Design By:
-- DNA Enterprises Inc
-- 269 West Renner Parkway
-- Richardson, TX 75080
--
-- File name : registers.vhd
-- Title : Registers
-- Module : Top-Level McEVM Control
-- Description :
-- This module contains all CPLD registers that are written from the
-- DSP or the PCI controller. These registers were located at the
-- top level of the EVM CPLD Abel source code.
--
-- DSP mapped registers are at base address CE1:0x0138xxxx/0x0178xxxx
-- (MAP0/MAP1).
--
-- DSP Control Register
-- (Address Offset = 0x0, DSP Offset = 0x00)
-- bit 7: RW: xcntl1
-- bit 6: RW: xcntl0

--- Modification History : ---

-- Revision: 0
-- Date: 03/31/98
-- Author: Don Curry (DNA)
-- Description: Initial conversion from ABEL version of EVM CPLD.

-- Revision: 1
-- Date: 05/01/98
-- Author: Don Curry (DNA)
-- Description: Added PCI and DSP semaphore register bits as well
-- as the OSC_B_FREQ register.
-- Revision: 2
-- Date: 05/03/98
-- Author: Don Curry (DNA)
-- Description: Changed NMISEL to always select host (0) since codec is no longer valid. Added McEVM specific registers.

This module combines the EVMCKSEL, EVMRESET and EVMSWMUX functions from the EVM CPLD Abel files.

The EVMCKSEL implements DSP source clock selection. The DSP source clock (CLKIN) can either be 33.25MHz or 50MHz. The two oscillator outputs are buffered using buffers with independent output enables. The outputs of these buffers are connected together. This module makes sure that there is never any contention on this signal by turning off both buffers for one clock period prior to turning on one. The clock used for this function is the free-running clock from Osc. A (33.25 MHz).

The EVMRESET controls the various types of reset signals that are used on the McEVM board. Signals are generated that reset the board, DSP, JTAG TBC and external daughterboard independently. All resets are
-- asserted on power-up, when the manual reset pushbutton is pressed and
-- when the board is in a software board reset under control of the host.
-- The host can reset the board, DSP and TBC. The DSP can reset the
-- external daughterboard.
--
-- The EVMSWMUX provides a multiplexer to switch between hardware DIP
-- switches and host software controllable registers for various modes.
-- The CPLD defaults to the DIP switches at power-up or board reset. The
-- multiplexer is controlled by the host software using the PCI mapped
-- CPLD SWBOOT registers SWSEL bit. A 0 (default) selects the DIP switch
-- and a 1 selects the software register bits.
--
-- Modification History :
--
-- Revision: 0
-- Date: 03/30/98
-- Author: Don Curry (DNA)
-- Description: Initial conversion from ABEL version of EVM CPLD.

This module contains the EVMDECODE functions from the EVM CPLD Abel files. This module provides the DSP EMIF memory decode to control async memory accesses to the CE1 memory space. The devices in the CE1 memory space include the CPLD registers, the PCI Controller, the PMIC MVIP Controller, the T1/E1 Transceiver and the expansion memory (daughterboard). Decode logic controls the data bus transceivers that connect the DSP’s EMIF data bus to the peripheral, PCI Add-On and external daughterboard data busses. The asynchronous memory control strobes from the DSP are synchronized for use by the PCI controller state machine. Async memory access ready (RDY) generation is implemented for each type device access in the CE1 memory space.

This module contains the EVMINT functions from the EVM CPLD Abel files.

This module controls the interrupts to the host (via the PCI Controller) and the C6201 DSP. The DSP host interrupt and the JTAG TBC can be used to interrupt the host. This module implements falling edge detectors to determine when these source interrupts occur to force a PCI mailbox interrupt in the S5933 PCI Controller which causes and INTA# host interrupt. Logic is included to implement a DSP NMI interrupt source. The PCI controller add-on IRQ# is passed to the DSP via its EXT_INT4 input. Additionally, PCI bus master read (EXT_INT5) and write (EXT_INT6) interrupts are generated by state machines in this module that monitor the PCI controllers FIFO FULL and EMPTY flags to determine when data can be transferred between the PCI Controller and DSP memory space. These interrupts can be used by the DSP to trigger ISR’s or more
typically used to trigger background DMA transfers. Optionally, the DSP could even poll these interrupts or the FIFO flags themselves to control data transfers.

The DSP can also be interrupted via the T1/E1 transceiver or the daughterboard. This module takes in the two interrupt sources (both active high, level interrupts) and generate a rising edge interrupt to the DSP (EXT_INT7). To clear the interrupts the DSP must write to the Interrupt control register with the appropriate bits set. If another interrupt is pending, another edge will be generated so that the interrupt can be serviced. The clear bits can also be used to mask interrupts from a particular source. If the clear bit is set no interrupts from that source are latched and thus cannot cause an interrupt to the DSP.

---

Modification History:

Revision: 0
Date: 04/02/98
Author: Don Curry (DNA)
Description: Initial conversion from ABEL version of EVM CPLD.

Texas Instruments Incorporated

Design By:
DNA Enterprises Inc
269 West Renner Parkway
Richardson, TX 75080

File name : pci_cntlr.vhd
Title : McEVM PCI Interface Controller
Module : Top-Level McEVM Control
Description :

This module contains the EVMPCI functions from the EVM CPLD Abel files.

This module controls the slave (target) interface between the PCI Controller and the JTAG TBC, DSP HPI and CPLD PCI registers. It also controls the interface for DSP EMIF accesses to the PCI controller which include PCI Bus Master read/write transfers. This module provides the state machine(s) necessary to control the signals that are required to transfer data between the PCI controller and the DSP. The CPLD only interfaces to the PCI controllers add-on bus interface and not the actual PCI bus.

Modification History :

Revision: 0
-- Date: 04/29/98
-- Author: Don Curry (DNA)
-- Description: Initial conversion from ABEL version of EVM CPLD.
--
-- Revision: 1
-- Date: 05/01/98
-- Author: Don Curry (DNA)
-- Description: Re-wrote entire state machine due to ensure what I did would work as I thought without any surprises.
--
-- Revision: 2
-- Date: 05/05/98
-- Author: Don Curry (DNA)
-- Description: Added state to HPI accesses during x1 mode to assure HDS1 pulse width requirements.
--
-- Revision: 3
-- Date: 08/07/98
-- Author: Don Curry (DNA)
-- Description: Changed add-on address from pci_apted_adr to ea_lo
-- Added multiplex feature for PTADR
-- Found tbca_hpi problem -- bit vector control shifted right by one. Fixed WFD
-- Revision: 4
-- Date: 08/10/98
-- Author: Bill Dempsey (DNA)
-- Description: Changed C6x write access to AMCC from 2 clk wide pulse to 1 clk wide pulse
--
-- Revision: 5
-- Date: 08/14/98
-- Author: Bill Dempsey (DNA)
-- Description: Found that back-to-back PTNUM=2 accesses without deassertion of PTATN caused state
-- machine to restart without asserting AMCC chip select 'ao_sel_l'

This appendix documents the EEPROM used on the 'C62x McEVM to initialize the AMCC S5933 peripheral component interconnect (PCI) controller’s configuration space registers.

The S5933 PCI controller provides the configuration registers required to support the PCI’s plug-and-play capability. The initialization of these registers is performed upon power up and system reset by the S5933, which clocks serial data in from the EEPROM using a two-wire, bidirectional data transfer. This automatic register initialization is performed since the S5933’s SNV pin is pulled up on the McEVM to indicate that a serial nonvolatile memory device is present.

Table D–1 summarizes the contents of the 1K-byte EEPROM. Multibyte default values are stored in least-significant-byte to most-significant-byte (little-endian) order. The 64-byte configuration information is stored in the EEPROM locations 0x40 to 0x7F. Locations 0x00 to 0x3F are reserved for future use by Texas Instruments. Locations 0x80 to 0x3FF are available for user-defined, nonvolatile storage that is accessible by both host and DSP software.
Table D–1. PCI Configuration EEPROM Summary

† These address offsets are available for general-purpose use. This is a total of 896 bytes.
A/D: See analog-to-digital.

adaptive differential pulse code modulation (ADPCM): A speech coding method that calculates the difference between two consecutive speech samples and encodes it using an adaptive filter to transmit at a lower rate than the standard 64-kbps pulse code modulation technique.

ADC: See analog-to-digital converter.

address: The logical location of program code or data stored in memory.

administrative privileges: Authority to set software and hardware access; includes access and privileges to install, manage, and maintain system and application software and directories on a network server or individual computer systems.

ADPCM: See adaptive differential pulse code modulation.

A-Law companding: See compress and expand (compand).

ALU: See arithmetic logic unit.

analog-to-digital (A/D): Conversion of continuously variable electrical signals to discrete or discontinuous electrical signals.

analog-to-digital converter (ADC): A converter with internal sample-and-hold circuitry used to translate an analog signal to a digital signal.
ANSI C: A version of the C programming language that conforms to the C standards defined by the American National Standards Institute.

application programming interface (API): A set of standard software function calls and data formats that application programs use to interact with other applications, device-specific drivers, or the operating system.

application-specific integrated circuit (ASIC): A custom chip designed for a specific application. It is designed by integrating standard cells from a library.

arithmetic logic unit (ALU): The section of the computer that carries out all arithmetic operations (addition, subtraction, multiplication, division, or comparison) and logic functions.

ASIC: See application-specific integrated circuit.

assembler: A software program that creates a machine language program from a source file that contains assembly language instructions, directives, and macros. The assembler substitutes absolute operation codes for symbolic operation codes, and absolute or relocatable addresses for symbolic addresses.

assert: To make a digital logic device pin active. If the pin is active low, then a low voltage on the pin asserts it. If the pin is active high, then a high voltage asserts it.

ball grid array (BGA): An integrated circuit package in which the input and output connections are solder balls arranged in a grid pattern.

base address register (BAR): A device configuration register that defines the start address, length, and type of memory space required by a peripheral component interconnect (PCI) device. The value written to this register during device configuration programs its memory decoder to detect accesses within the indicated range.

basic input/output system (BIOS): A firmware program that is responsible for power-on testing and initialization of a computer. In addition, it may provide runtime services for operating systems.

BBS: See bulletin board service.

benchmarking: A type of program execution that allows you to track the number of CPU cycles consumed by a specific section of code.
**BGA:** See ball grid array.

**big endian:** An addressing protocol in which bytes are numbered from left to right within a word. More significant bytes in a word have lower numbered addresses. Endian ordering is specific to hardware and is determined at reset. See also **little endian**.

**BIOS:** See basic input/output system.

**bit:** A binary digit, either 0 or 1.

**boot:** The process of loading a program into program memory.

**boot mode:** The method of loading a program into program memory. The 'C62x DSP supports booting from external ROM or the host port interface (HPI).

**bulletin board service (BBS):** An electronic bulletin board that allows users to post and read messages and download software.

**bus master:** A device capable of initiating a data transfer with another device.

**byte:** A sequence of eight adjacent bits operated upon as a unit.

**CBT:** See crossbar technology.

**CD-ROM:** See compact disc read-only memory.

**central processing unit (CPU):** The CPU is the portion of the processor involved in arithmetic, shifting, and Boolean logic operations, as well as the generation of data- and program-memory addresses. The CPU includes the central arithmetic logic unit (CALU), the multiplier, and the auxiliary register arithmetic unit (ARAU).

**channel service unit (CSU):** A device used to connect a digital phone line, such as T1/E1, coming in from the phone company to another device producing a digital signal.

**clock cycle:** A cycle based on the input from the external clock.

**clock mode (clock generator):** One of the modes that sets the internal CPU clock frequency to a fraction or multiple of the frequency of the input clock signal CLKIN.

**clock modes:** Options used by the clock generator to change the internal CPU clock frequency to a fraction or multiple of the frequency of the input clock signal.
Glossary

**CMOS:** See *complementary metal oxide semiconductor.*

**coder-decoder or compression/decompression (codec):** A device that codes in one direction of transmission and decodes in another direction of transmission.

**common object file format (COFF):** A system of object files configured according to a standard developed by AT&T. These files are relocatable in memory space. The 'C62x code generation tools generate COFF files.

**compact disc read-only memory (CD-ROM):** A 4.7-inch optical disk that can hold as much as 660M bytes of digital data. A CD-ROM can store digitized audio, image, video, text, and application data.

**compiler:** A translation program that converts a high-level language set of instructions into a target machine's assembly language.

**complementary metal oxide semiconductor (CMOS):** An integrated circuit technology that uses complementary transistors to efficiently charge and discharge capacitive loads in both the positive and negative directions and dissipates power only on transitions.

**complex programmable logic device (CPLD):** A digital, user-configurable integrated circuit used to implement custom logic functions.

**compress and expand (compand):** A quantization scheme for audio signals in which the input signal is compressed and then, after processing, is reconstructed at the output by expansion. There are two distinct companding schemes—A-law, used in Europe, and μ-law, used in the United States.

**CPLD:** See *complex programmable logic device.*

**crossbar technology (CBT):** High-speed bus-connect devices that are useful for bus isolation, multiplexing, and voltage translation. These devices have an on-state resistance of 5 ohms and a propagation delay of 250 ps.

**CPU:** See *central processing unit.*

**CSU:** See *channel service unit.*
D/A: See digital-to-analog.

DAC: See digital-to-analog converter.

daughterboard: A circuit board that connects to a motherboard to provide additional capabilities and/or interfaces. See also motherboard.

dB: See decibels.

debugger: A software interface used to identify and eliminate mistakes in a program.

decibels (dB): A unit for measuring the level of signal relative to a defined reference signal that follows it. For example, the notation dBm indicates a signal power level relative to a 1 milliwatt reference signal.

device driver: Software that enables computer hardware to communicate with a device. A device driver may also translate data and call other drivers to actually send data to a device.

device ID: Every peripheral component interconnect (PCI) device must have a device ID configuration register to identify itself.

digital signal processor (DSP): A semiconductor that turns analog signals—such as sound or light—into digital signals, which are discrete or discontinuous electrical impulses, so that they can be manipulated.

digital-to-analog (D/A): Conversion of discrete or discontinuous electrical signals to continuously variable signals. See also digital-to-analog converter.

digital-to-analog converter (DAC): A device that converts a signal represented by a series of numbers (digital) to a continuously varying signal (analog). See also digital-to-analog.

DIP: See dual in-line package.

direct memory access (DMA): A mechanism whereby a device other than the host processor contends for, and receives, mastery of the memory bus so that data transfers can take place independent of the host.

DLL: See dynamic link library.

DMA: See direct memory access.

doubleword (DWORD): The PCI (host) defines a doubleword as a 32-bit value. See also word and halfword.
driver: See device driver.

DSP: See digital signal processor.

dual in-line package (DIP): A common rectangular chip housing with leads (pins) on both long sides.

DWORD: See doubleword.

dynamic link library (DLL): A Windows software library that is linked dynamically at run time, rather than statically at compile time. DLLs can be shared among multiple applications and be replaced with newer versions without requiring the applications to be recompiled.

EEPROM: See electrically-erasable programmable read-only memory.

electret microphone: A condenser microphone that requires an external power source.

electrically-erasable programmable read-only memory (EEPROM): A nonvolatile memory device that can be programmed in-circuit and have its contents selectively changed. Although its name includes read-only, it supports both read and write accesses.

electrostatic discharge (ESD): Discharge of a static charge on a surface or body through a conductive path to ground, which can be damaging to integrated circuits.

EMIF: See external memory interface.

erasable programmable read-only memory (EPROM): A nonvolatile memory device that can be erased with exposure to ultraviolet light. The device can be randomly accessed, but it is read only.

ESD: See electrostatic discharge.

evaluation module (EVM): A board and software tools that allow the user to evaluate a specific device.

expansion interface: An interface that allows additional capabilities to be added to a base product.

external interrupt: A hardware interrupt triggered by a specific value on a pin.

external memory interface (EMIF): The boundary between the CPU and external memory through which information is conveyed.
first in, first out (FIFO): A queue; a data structure or hardware buffer from which items are taken out in the same order they were put in. A FIFO is useful for buffering a stream of data between a sender and receiver that are not synchronized; that is, the sender and receiver are not sending and receiving at exactly the same rate. If the rates differ by too much in one direction for too long, the FIFO becomes either full (blocking the sender) or empty (blocking the receiver).

flag: A binary status indicator whose state indicates whether a particular condition has occurred or is in effect.

Flash memory: Nonvolatile read-only memory that is electronically erasable and programmable.

flexible MVIP integrated circuit (FMIC): Device which provides a complete MVIP-compliant interface between the MVIP bus and a variety of processors, telephony interfaces and other circuits. It also provides a 384 x 384 switching matrix between the MVIP bus and four local data streams.

halfword: The ’C62x DSP defines a halfword as a 16-bit data value. See also doubleword and word.

handle: An identifier used by software to reference a file or device.

high-level language (HLL): A general-purpose language that can be used to program a microprocessor rather than using a low-level, machine-dependent language.

host: A device to which other devices (peripherals) are connected and that generally controls those devices.

host port interface (HPI): A 16-bit parallel interface that the host uses to access the DSP’s memory space.

identifier (ID): A field that contains a resource-table index, a sequence number, and a resource-type code; it identifies a kernel resource such as a port, semaphore, or task.

IEEE 1149.1 standard: “IEEE Standard Test Access Port and Boundary-Scan Architecture”, first released in 1990. See also JTAG.
Industry Standard Architecture (ISA): An industry-standard 8/16-bit bus used in IBM™ compatible desktops. It provides a theoretical maximum data transfer rate of 8.33M bytes per second.

initiator: When a PCI bus master has arbitrated for and won access to the PCI bus, it becomes the initiator of a transaction.

Institute of Electrical and Electronic Engineers (IEEE): A publishing and standards-making body focused on advancing the theory and practice of electrical, electronics, computer engineering, and computer science.

in-system programmable (ISP): The ability to program and reprogram a device on a circuit board.

Integrated Services Digital Network (ISDN): A worldwide digital communications network evolving from existing telephone services. Its goal is to replace current telephone lines that require DA conversions with totally digital switching and transmission facilities capable of carrying a variety of data—from voice to computer transmissions, music, and video. The ISDN is built on two main types of communications channels: a B channel, which carries data at 64 Kb/s, and a D channel, which carries control information at either 16 or 64 Kb/s. Computers and other devices connect ISDN lines through simple, standardized interfaces.

integrated switching regulator (ISR): A complete switch-mode power supply in a modular, board-mounted package.

internal interrupt: A hardware interrupt caused by an on-chip peripheral.

interrupt: A signal sent by hardware or software to a processor requesting attention. An interrupt tells the processor to suspend its current operation, save the current task status, and perform a particular set of instructions. Interrupts communicate with the operating system and prioritize tasks to be performed.

interrupt service routine: A module of code that is executed in response to a hardware or software interrupt.

ISDN: See Integrated Services Digital Network.

ISP: See in-system programmable.

ISR: See integrated switching regulator.
**Joint Test Action Group (JTAG):** The Joint Test Action Group was formed in 1985 to develop economical test methodologies for systems designed around complex integrated circuits and assembled with surface-mount technologies. The group drafted a standard that was subsequently adopted by IEEE as IEEE Standard 1149.1-1990, “IEEE Standard Test Access Port and Boundary-Scan Architecture.”

**kilohertz (kHz):** One thousand hertz, or cycles per second, used to indicate the frequency of a clock signal.

**latch phase:** The phase of a CPU cycle during which internal values are held constant.

**LBO:** See line build out.

**light emitting diode (LED):** A semiconductor chip that gives off visible or infrared light when activated.

**line build out (LBO):** Selectable output attenuation with typical loss of 0.0, 7.5 and 15 dB at 772 kHz.

**line interface unit (LIU):** A device or a part of a device responsible for interfacing to a digital network (T1/E1) line.

**linker:** A software tool that combines object files to a form an object module, which can be loaded into memory and executed.

**little endian:** An addressing protocol in which bytes are numbered from right to left within a word. More significant bytes in a word have higher numbered addresses. Endian ordering is specific to hardware and is determined at reset. See also big endian.

**LIU:** See line interface unit.

**load:** To enter data into storage or working registers.

**loader:** A device that places an executable module into system memory.
mA: See milliamp.

macro: A sequence of statements or instructions that is represented by a symbolic symbol.

μF: See microfarad.

μ-Law companding: See compress and expand (compand).

mailbox: A 32-bit register that provides a simple communication method to pass messages between the host and DSP software. Multiple mailboxes are typically available to support bidirectional, multiword message transfers.

maskable interrupt: An interrupt that can be enabled or disabled through software.

master clock output signal (CLKOUT1): The output signal of the on-chip clock generator. The CLKOUT1 high pulse signifies the CPU’s logic phrase (when internal values are changed), while the CLKOUT1 low pulse signifies the CPU’s latch phase (when the values are held constant).

Mbps: See megabit per second.

McBSP: See multichannel buffered serial port.

McEVM: A multichannel communications development board and software tools that allow the user to evaluate a specific device.

megabit per second (Mbps): A million bits of data per second.

megahertz (MHz): One million hertz, or cycles per second, used to indicate the frequency of a clock signal.

memory map: A graphical representation of a computer system’s memory, showing the locations of program space, data space, reserved space, and other memory-resident elements.

memory-mapped register: An on-chip register mapped to an address in memory. Some memory-mapped registers are mapped to data memory, and some are mapped to input/output memory.

MHz: See megahertz.

microfarad (μF): One-millionth of a farad, which is the basic unit of capacitance.
microsecond (μs): One-millionth of a second.

milliamp (mA): One-thousandth of an ampere, which is the basic unit of current.

millimeter (mm): One-thousandth of a meter.

million instructions per second (MIPS): A unit of instruction execution speed of a computer.

millisecond (ms): One-thousandth of a second.

millivolts root mean square (mVrms): One-thousandth of a volt root mean square. See also volts root mean square.

MIPS: See million instructions per second.

mm: See millimeter.

most significant byte (MSbyte): The byte in a multibyte word that has the most influence on the value of a word.

motherboard: The main circuit board that contains the processor, main memory, circuitry, bus controller, connectors, and primary components of the computer. See also daughterboard.

μs: See microsecond.

ms: See millisecond.

MSbyte: See most significant byte.

multichannel buffered serial port (McBSP): A standard serial port interface found on 'C62x devices. It provides full-duplex communication, double-buffered data registers, independent transmit and receive framing and clocking, direct interface to industry-standard serial devices, internal and external clock support, and an autobuffering capability using a DMA controller.

multiplexing: A process of transmitting more than one set of signals at a time over a single wire or communications link. (Also known as muxing.)

Multi-Vendor Integration Protocol (MVIP): A family of standards that allows products from different vendors to interoperate within a computer or group of computers. The MVIP bus is a telephony bus that provides 256 full-duplex voice channels (16 streams of 32 timeslots) over a ribbon cables between PC boards.

mutex: A mutual exclusion semaphore used to restrict access to a resource.
Glossary

MVIP: See Multi-Vendor Integration Protocol.

mVrms: See millivolts root mean square.

N

nanosecond (ns): One-billionth of a second, the basic unit of time.

nonmaskable interrupt (NMI): An interrupt that uses the same logic as the maskable interrupts, but can be neither masked nor disabled. It is often used as a soft reset.

nonvolatile random access memory (NVRAM): A type of random access memory that retains its data when its power source is turned off, providing nonvolatile storage.

O

object file: A file that has been assembled or linked and contains machine language object code.

off chip: A device external to the device.

on chip: An element or module internal to the device.

P

parallel debug manager (PDM): A program used for creating and controlling multiple debuggers for the purpose of debugging code in a parallel-processing environment.

PC: Personal computer.

PCI: See peripheral component interconnect.

PCM: See pulse code modulation.

PDM: See parallel debug manager.

peripheral component interconnect (PCI): A high-speed local bus that supports data-transfer speeds of up to 132M bytes per second at 33 MHz.

phase-locked loop (PLL): A unit within a system that uses phase to lock onto a signal to ensure synchronous clocking of digital signals.
pitch: The distance between successive centers of leads of a component package.

plastic quad flat pack (PQFP): A low-profile, surface-mount integrated circuit package that is plastic and has leads (pins) on all four sides.

PLL: See phase-locked loop.

poll: A continuous test used by the program until a desired condition is met.

PQFP: See plastic quad flat pack.

profiling environment: A special debugger environment that provides a method for collecting execution statistics about specific areas in application code.

pulse code modulation (PCM): The most common method of encoding an analog voice signal into digital data. Voice signals are encoded into 8-bit data samples at an 8-kHz sample rate, resulting in a 64-kbps digital data stream.

random-access memory (RAM): A memory element that can be written to as well as read from.

read-only memory (ROM): A semiconductor storage element containing permanent data that cannot be changed.

ready: A task state indicating that the task either is currently executing or is able to execute as soon as it acquires the processor.

real time: The actual time during which the physical process of computation transpires in order that results of the computation interact with a physical process.

reduced instruction set computer (RISC): A computer whose instruction set and related decode mechanism are much simpler than those of microprogrammed complex instruction set computers. The result is a higher instruction throughput and a faster real-time interrupt service response from a smaller, cost-effective chip.

register: A small area of high-speed memory, located within a processor or electronic device, that is used for temporarily storing data or instructions. Each register is given a name, contains a few bytes of information, and is referenced by programs.
reset: A means to bring processors to known states by setting registers and control bits to predetermined values and signaling execution to start at a specified address.

ring 0: Highest level of privilege available on an Intel processor that defines what data can be accessed, what code in memory can be executed, and what machine instructions can be executed by a program. Low-level device drivers run at ring 0. See also ring 3.

ring 3: Lowest level of privilege available on an Intel processor that defines what data can be accessed, what code in memory can be executed, and what machine instructions can be executed by a program. High-level user-mode applications and DLL run at ring 3. See also ring 0.

RISC: See reduced instruction set computer.

ROM: See read-only memory.

sample rate: The rate at which the audio codec samples audio data. Usually specified in hertz (samples per second).

SBSRAM: See synchronous burst static random-access memory.

SDRAM: See synchronous dynamic random-access memory.

slave: Another name for the target being addressed during a PCI transaction.

static random-access memory (SRAM): Fast memory that does not require refreshing, as DRAM does. It is more expensive than DRAM, though, and is not available in as high a density as DRAM.

structure: A collection of one or more variables grouped together under a single name.

surface-mount technology: A method of assembling printed wiring boards where components are mounted onto the surface rather than through holes.

synchronous burst static random-access memory (SBSRAM): High-performance SRAM device with accesses that are synchronized to a microprocessor clock and includes a burst address counter.

synchronous dynamic random-access memory (SDRAM): High-performance DRAM device with accesses that are synchronized to a microprocessor clock and support for page bursts.

syntax: The grammatical and structural rules of a language. All higher-level programming languages possess a formal syntax.
**T1/E1:** T1 is a digital transmission link with a capacity of 1.544 Mbps. It uses two pairs of normal twisted-wires and can handle 24-voice conversations, each digitized using mu-law coding at 64 kbps. T1 is used in USA, Canada, Hong Kong, and Japan. E1 is a digital transmission link with a capacity of 2.048 Mbps. It is the European equivalent of T1. It can handle 30-voice conversations, each digitized using A-law coding at 64 kbps.

**target:** When related to PCI, it is the device that is the target of a PCI transaction initiated by a PCI bus master. When related to the debugger, the DSP is the target of an emulation access.

**target memory:** Physical memory in a device into which executable object code is loaded.

**TDM:** See time-division multiplexed.

**test bus controller (TBC):** Application-specific integrated circuit that controls an IEEE 1149.1–1990 (JTAG) serial-test bus to support production testing and in-system microprocessor emulation. The TBC provides control of the DSP and access to all of its registers and memory.

**thin quad flat pack (TQFP):** A very low-profile, surface-mount integrated circuit package that is plastic and has leads (pins) on all four sides.

**thread of execution:** A schedulable unit of execution in a multitasking system. The term refers specifically to the progressive execution of a program element; it excludes other attributes, such as the system resources allocated to a task or process.

**time-division multiplexed (TDM):** The process by which a single serial bus is shared by multiple devices with each device taking turns to communicate on the bus. The total number of time slots (channels) depends on the number of devices connected. During a time slot, a given device may talk to any combination of devices on the bus.

**timer:** A programmable peripheral used to generate pulses or to time events.

**TQFP:** See thin quad flat pack.

**transistor-transistor logic (TTL):** A family of logic devices that are made with bipolar junction transistors and resistors. A TTL low level is defined as a voltage level below 0.4 volts. A TTL high level is defined as a voltage level above 2.4 volts.

**tri-state:** High impedance.
V:  See volt.

VBAP:  See voice-band audio processor.

$V_{dc}$:  See volts direct current.

VelociTI:  Architecture developed by Texas Instruments that features very long instruction words.

vendor ID:  Every PCI device must have a vendor ID configuration register that identifies the vendor of the device.

very long instruction word (VLIW):  Architecture using words between the sizes of 256 bits and 1024 bits.

virtual device driver (VxD):  A 32-bit, ring-0 module that virtualizes hardware for ring-3 modules to provide a primary interface to hardware or specialized software services.

VLIW:  See very long instruction word.

voice-band audio processor (VBAP):  A voice codec device that provides filtering, analog-to-digital and digital-to-analog conversion with interfaces to a microphone, speaker, and serial, digital interface. It can operate in either mu-law or A-law companding or 13-bit linear modes.

volt (V):  The unit of voltage, or potential difference.

volts direct current ($V_{dc}$):  The voltage measurement of a direct current signal.

volts peak-to-peak ($V_{pp}$):  A measurement of a signal that indicates the difference between its maximum and minimum voltage values.

volts root mean square ($V_{rms}$):  A measurement of a periodic signal that indicates the effective voltage at which a direct current voltage would deliver the same average power. This measurement provides a method for comparing the power delivered by different waveforms.

VxD:  See virtual device driver.
**Win32:** The 32-bit application programming interface for both Windows 95 and Windows NT.

**word:** A character or bit string considered as an entity. The length of the word is machine-dependent. The ’C62x DSP defines a word as a 16-bit data value. The PCI (host) defines a word as a 16-bit data value. See also doubleword and halfword.

**XDS510:** A hardware emulator that provides a scan-path connection to a DSP for source code debugging.

**xDSL:** A generic name (x is the generic) for digital subscriber line equipment and services. Asymmetric DSL (ADSL) is one of the more popular types, providing up to 6 Mbsp downstream and 640 kbps upstream data rates using standard twisted pair wiring.
add-on FIFO register port (AFIFO) 1-29
add-on general control/status register (AGCSTS) 1-29
add-on incoming mailbox registers (AIMB1–AIMB4) 1-29
add-on interrupt control register (AINT) 1-29
add-on mailbox empty/full status register (AMBEF) 1-29
add-on outgoing mailbox registers (AOMB1–AOMB4) 1-29
AFIFO register 1-29
AGCSTS register 1-29
AIMB1–AIMB4 registers 1-29
