The Non-Euclidean Euclidean Algorithm and Curve Lengths on Pairs of Pants

> Jane Gilman Rutgers-Newark

October 3, 2015

THE SET-UP

 $G = \langle A, B \rangle$, a non-elementary subgroup of $Isom(\mathbb{H}^2)$, equivalently $PSL(2, \mathbb{R})$.

The $PSL(2, \mathbb{R})$ geometric algorithm answers the questions as to whether *G* discrete or not discrete.

Begin with A and B an ordered set of generators. There exists integers $[n_1, n_2, ..., n_t]$ such that the sequence

$$(A,B)
ightarrow (B^{-1},A^{-1}B^{n_1})
ightarrow (B^{-n_1}A,B(A^{-1}B^{n_1})^{n_2})
ightarrow \cdots
ightarrow (ilde{A}, ilde{B})$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Begin with A and B an ordered set of generators. There exists integers $[n_1, n_2, ..., n_t]$ such that the sequence

$$(A,B)
ightarrow (B^{-1},A^{-1}B^{n_1})
ightarrow (B^{-n_1}A,B(A^{-1}B^{n_1})^{n_2})
ightarrow \cdots
ightarrow (ilde{A}, ilde{B})$$

stops at a pair (\tilde{A}, \tilde{B}) after a finite number of replacements and says (i) G is discrete (ii) G is not discrete, or (iii) G is not free.

Begin with A and B an ordered set of generators. There exists integers $[n_1, n_2, ..., n_t]$ such that the sequence

$$(A,B)
ightarrow (B^{-1},A^{-1}B^{n_1})

Notation for Algebraic and Geometric Quantities

Hyperbolic Transformation XAxis Ax_X Translation length T_X The matrix of X has a trace Tr X. Tr X and T_X related by

$$\cosh \frac{T_X}{2} = \frac{1}{2} \text{Tr X}$$

Theorem

The Non-Euclidean Euclidean Algorithm (G-2013) If one applies the Euclidean algorithm to the non-Euclidean translation lengths of the generators at each step, the output is the F-sequence $[n_1, ..., n_k]$.

$$n_1 = \left[\frac{T_A/2}{T_B/2}\right]$$

where [] denotes the greatest integer function and

$$n_2 = [\frac{T_B}{T_D/2}]$$
 where $D = A^{-1}B^{n_1}$

and

$$n_t = \left[\frac{T_{A_t}/2}{T_{B_t}/2}\right]$$

where (A_t, B_t) is the pair of generators at step t in theorem 3.

DRAW

Given A and B hyperbolic transformations, let L be their common perpendicular.

Given A and B hyperbolic transformations, let L be their common perpendicular.

Let R_M , denote the half-turn about (or reflection in) the geodesic M

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Given A and B hyperbolic transformations, let L be their common perpendicular.

Let R_M , denote the half-turn about (or reflection in) the geodesic M

There are geodesics L_A and L_B perpendicular to the axes of A and B such that

$$A = R_L \circ R_{L_A}$$
 and $B = R_L \circ H_{R_B}$

$$A^{-1}B = R_{L_A} \circ R_{L_B}$$

L_B separates L and L_A

 L_B separates L and L_A

there are geodesics

 $L_{B^2}, L_{B^3}....$

perpendicular to the axis of B whose distance apart is half of \mathcal{T}_B and such that

 L_B separates L and L_A

there are geodesics

 $L_{B^2}, L_{B^3}....$

perpendicular to the axis of B whose distance apart is half of \mathcal{T}_B and such that

$$B = R_{L_B} \circ R_{L_{B^2}}$$

 L_B separates L and L_A there are geodesics

 $L_{B^2}, L_{B^3}....$

perpendicular to the axis of B whose distance apart is half of T_B and such that

$$B = R_{L_B} \circ R_{L_{B^2}} = R_{L_{B^2}} \circ R_{L_{B^3}} = \cdots$$

 L_B separates L and L_A there are geodesics

 $L_{B^2}, L_{B^3}....$

perpendicular to the axis of B whose distance apart is half of T_B and such that

$$B = R_{L_B} \circ R_{L_{B^2}} = R_{L_{B^2}} \circ R_{L_{B^3}} = \cdots$$

We can take the smallest *n* such that L_{B^n} separates but $L_{B^{n+1}}$ does not.

 L_B separates L and L_A there are geodesics

 $L_{B^2}, L_{B^3}....$

perpendicular to the axis of B whose distance apart is half of T_B and such that

View the algorithm as an unwinding procedure. Run the algorithm backwards as a winding procedure. Can wind or unwind: go from (A, B) to (\tilde{A}, \tilde{B}) or from (\tilde{A}, \tilde{B}) to (A, B)

Unwinding sequence $[n_1, ..., n_t] \implies$ winding sequence $[-n_t, ..., -n_1]$.

often write with positive integers and simply note winding.

Primitive curves and rationals

◆□ ▶ < 圖 ▶ < 圖 ▶ < 圖 ▶ < 圖 • 의 Q @</p>

Primitive curves and rationals

Theorem

(G-Keen 2002) Primitive curves correspond to rational numbers. A primitive curve will have a winding sequence $[m_1, ..., m_t]$ for some integer t. Label the curve γ_r where r is the rational with continued fraction entries $[0, m_1, ..., m_r]$

Theorem 0.3 can be rewritten as

Theorem (Winding and Curve Lengths) Let W be a curve corresponding to a primitive word in G that is not conjugate to a stopping generator. LetL(W) be its length and $[n_1, ..., n_t]$ its winding sequence. Assume that $L(S_0)$ is the longest length of any simple closed curve on the surface. Then

 $(\prod_{i=1}^t n_i)L(S_0) \leq L(W) \leq (\prod_{i=1}^t (n_i + 1))L(S_0).$

Essential self-intersections for primitive curves

Essential self-intersections for primitive curves

Definition

If W is any closed curve on a pair of pants, it will have a certain number of essential self-intersections, that is, self-intersections along seams of the pair of pants. All other self-intersection are *trailing intersections*. Denote the number of essential self-intersections by

Int(W)

Essential self-intersections for primitive curves

Definition

If W is any closed curve on a pair of pants, it will have a certain number of essential self-intersections, that is, self-intersections along seams of the pair of pants. All other self-intersection are *trailing intersections*. Denote the number of essential self-intersections by

Int(W)

or by

Int(r)

if $W = \gamma_r$ where γ_r is the curve with winding sequence $[m_1, ..., m_t]$ and r is the rational with continued fraction entries $[0, m_1, ..., m_t]$

Inductive formula for Int(r)

Theorem

(G-Keen 2002) (inductive formula for lnt(r)) We let lnt(r) denote the number of essential self-intersections of the curve with winding sequence $[n_1, ..., n_t]$, where r the corresponding rational and $r_k = [n_0, ..., n_k]$ its k-th approximent. Let $r_k = p_k/q_k$ where p_k is the numerator and q_k the denominator of the approximent and r_k is given in lowest terms.

Then the essential self-intersection numbers are given inductively as follows:

$$Int(\alpha_{0}) = 0, Int(\beta_{0}) = 0, Int(\alpha_{0}^{-1}\beta_{0}) = 0, Int(\alpha_{0}\beta_{0}) = 1, Int(\alpha_{0}\beta_{0}^{2}) = Int_{p_{k+1}/q_{k+1}} = 1 + n_{k+1} \cdot Int_{p_{k}/q_{k}} + Int_{p_{k-1}/q_{k-1}}$$

Theorem (G-2015) (Essential self-intersection number and curve length) If $L(\gamma)$ denotes the length of a curve γ and α_0 is the shortest simple closed curve on the surface with γ_0 , the longest,

 $Int(r) \times L(\alpha_0) \leq L(\gamma_r) \leq (Int(r+1)) \times L(\gamma_0)$

Theorem (G-2015) (Essential self-intersection number and curve length) If $L(\gamma)$ denotes the length of a curve γ and α_0 is the shortest simple closed curve on the surface with γ_0 , the longest,

$$Int(r) \times L(\alpha_0) \leq L(\gamma_r) \leq (Int(r+1)) \times L(\gamma_0)$$

Proof.

Basically bounded the number times the curve might go around the shortest simple curve and the longest simple curve.
