ヘロト ヘアト ヘヨト

This is joint work with Mariela Carvacho (U. Tecnica F. Santa Maria, Chile).

Let  $Z_2^k \equiv$  the elementary abelian 2-group of rank k > 2.

We consider  $Z_2^k$  actions on surfaces of genus g > 1, having branch data  $(0; 2, \stackrel{R}{\dots}, 2) = (0; R)$ , that is:

- the quotient surface is a sphere (genus 0);
- there are  $R \ge k + 1$  branch points (all branch indices = 2), on the quotient sphere.
- the action takes place in genus  $g = 2^{k-2}(R-4) + 1$ .

Equivalently, we consider surface-kernel epimorphisms

$$ho: \mathsf{\Gamma}(\mathsf{0}; R) o Z_{\mathsf{2}}^k$$

specified by sets of *R* elements of  $Z_2^k$  which

- generate the group;
- whose sum is the identity element.

(a.k.a. 'generating vectors.')

 $\rho$  may be pre- or post-composed with group automorphisms; the generating vectors so obtained constitute a topological equivalence class of action.

We represent  $Z_2^k$  as the vector space of dimension k over the field with two elements (0, 1), hence:

- Elements are (0, 1) column vectors with k entries;
- the identity  $\overline{0}$  (or  $\overline{0}_k$ ) is the column of all zeroes;
- a generating vector is a  $k \times R$  matrix M of rank k with rowsum  $\overline{0}$ .

Here,

- 'rowsum' = the column vector obtained by summing (mod 2) across the rows;
- 'matrix' means an unordered collection of columns; multiplicities are allowed.

It is convenient to compress a generating matrix M into a dependent set  $\mathcal{D}_M$  in the matroid  $Z_2^k - \{\overline{0}\}$ , by retaining only columns of odd multiplicity, listed once each.

- if there are no columns of odd multiplicity,  $\mathcal{D}_M = \emptyset$ ;
- if not empty,  $\mathcal{D}_M$  has at least 3 columns;
- rowsum  $\mathcal{D}_M$  = rowsum  $M = \overline{0}$  because (mod 2):
  - columns of even multiplicity in *M* do not contribute to the rowsum;
  - columns of odd multiplicity contribute as if they occurred only once.

Up to change of basis and columnwise reordering,  $D_M$ , if not empty, is a  $k \times k_0$  matrix of rank *r* of the form

$$\mathcal{D}_M \approx \underbrace{\begin{bmatrix} I_r & \mathbf{A} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}}_{k_0} \qquad 2 \le r \le \min\{k, k_0 - 1\}$$

where

- *k*<sub>0</sub> ≠ 1, 2 is the number of distinct columns of *M* with odd multiplicity;
- A is an  $r \times (k_0 r)$  matrix with rowsum =  $\overline{1}_r$ .

The two parameters

•  $k_0 = \#$  columns of odd multiplicity in *M*;

•  $k_1 = \#$  columns of even multiplicity in *M*;

must satisfy

•  $k_0 \neq 1, 2$  (for dependence of  $\mathcal{D}_M$ );

•  $k_0 + k_1 \ge k + 1$  (for generation of  $Z_2^k$ ).

A further necessary condition (if  $\mathcal{D}_M \neq \emptyset$ ):

• existence of a  $r \times (k_0 - r)$  matrix A with rowsum  $\overline{1}_r$  where  $2 \le r \le \min\{k_0 - 1, k\}$  (if  $r \ne 0$ ).

## Main Theorem (Carvacho, W.)

There is a  $Z_2^k$  action, k > 2, with branch data (0; R) if and only if R admits an additive partition into positive integers, with  $k_0$  odd parts and  $k_1$  even parts, satisfying the following conditions:

N1 
$$k \le k_0 + k_1 \le 2^k - 1;$$
  
N2 if  $k_0 + k_1 = k$ , then  $k_0 = 0;$   
N3  $k_0 \ne 1, 2, 2^k - 3, 2^k - 2.$ 

N.B.: the actual partition (hence R, hence the genus of the action) is not specified – only the partition type

 $\{k_0 \text{ odd parts}, k_1 \text{ even parts}\}.$ 

Comments on the Theorem

 The number of partition types which satisfy the Theorem's conditions (for fixed k) is finite, in fact, equal to

$$2^{2k-1}-3(2^{k-1}-1)-\frac{k(k-1)}{2};$$

- Actions of the same partition type occur in infinitely many genera (since infinitely many *R* admit a partition of a given type.)
- topologically equivalent actions have the same partition; in particular the same partition type;
- hence partition types define a coarse topological equivalence with finitely many equivalence classes.

< (**1**) > < ∃ >

## Comments on the PROOF

- 1. Why do partitions arise at all?
  - Each of the *R* branch points on the quotient sphere has  $2^{k-1}$  preimages, each fixed by a  $Z_2$  subgroup;
  - 2 such a subgroup has  $2g + 2 4\gamma = i(2^{k-1})$  for some *i*;
  - the total number of fixed points is

$$R(2^{k-1}) = \sum_{i=0} m_i (2g + 2 - 4\gamma(i)),$$

where  $m_i$  is the number of  $Z_2$  subgroups acting with quotient genus  $\gamma(i)$ ;

• cancelling  $2^{k-1}$  yields the finite partition

$$R=\sum_{i\geq 1}m_i\cdot i,$$

into positive parts *i*, where  $m_i$  is the multiplicity of the part *i*.

2. NECESSITY of conditions N1-N3 on the partition type is rather easy to see;

3. SUFFICIENCY :

one has to exhibit at least one compression of the form

$$\mathcal{D}_M \approx \underbrace{\begin{bmatrix} I_r & \mathbf{A} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}}_{k_0}$$

for each admissible partition type  $\{k_0, k_1\}$   $(k_0 \neq 0)$ ;

• the trickiest construction is A (which must have rowsum =  $\overline{1}_r$  and column weights  $\geq 2$ ).

'column weight' = # of ONES in the column.

Consider again

$$\mathcal{D}_M \approx \underbrace{\begin{bmatrix} I_r & \mathbf{A} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}}_{k_0} \qquad 2 \leq r \leq \min\{k, k_0 - 1\}.$$

- If r < k,  $k_0 \le 2^r 1$ . Moreover,  $k_0 \ne 2^r 2$ ,  $2^r 3$  (since  $Z_2^r$  contains no dependent sets of complementary size 1, 2, resp.)
- It suffices to assume r = k.
- if  $k_0 = 2^k 1$ ,  $\mathcal{D}_M = Z_2^k \{\overline{0}\}$  and A is determined;
- $k_0 \neq 2^k 2, 2^k 3$  (as above).

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 ののの

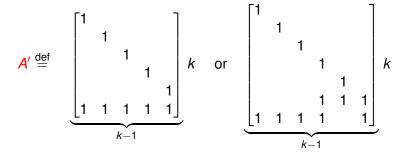

Thus we may assume  $k + 1 \le k_0 \le 2^k - 4$ , that is,

$$\mathcal{D}_M \approx \underbrace{\left[\begin{array}{c|c} I_k & A \end{array}\right]}_{k+1 \leq k_0 \leq 2^k - 4}$$

(In particular,  $k \ge 4$ ).

CLAIM: *A*, with rowsum  $= \overline{1}_k$ , and column weights  $\ge 2$ , can always be constructed.

If A has up to k − 1 columns a 'sparse' (= fewest ONES) matrix A can be obtained by 'telescoping' k × (k − 1) matrices of the form(s):

(k even, resp., odd: here 6, resp. 7)

'Telescoping' = successively adding the last two columns.

.≣⇒

## • For an A with $n \ge k$ columns, let

$$m = mk + t$$
,  $0 \le t < r$ 

and put

$$A = \underbrace{\left[ (A')_t \mid B_1 \mid \ldots \mid B_m \right]}_n,$$

where

- $(A')_t = A'$  telescoped to *t* columns (or  $= \emptyset$  if t = 0);
- each B<sub>j</sub>'s is a distinct 'k-block' = k-set of cyclic permutations of a non-periodic column (of weight > 2).

< 同 > < 臣 > < 臣 > …

 It suffices to consider k<sub>0</sub>'s of approximately half the maximum value:

$$k_0 \leq \frac{2^k - 2}{2} = 2^{k-1} - 1$$

(REASON: the complement of a dependent set in  $Z_2^k - \overline{\{0\}}$  is also a dependent set.)

In constructing

$$\mathcal{D}_{M} = \begin{bmatrix} I_{k} \mid (A')_{t} \mid B_{1} \mid \dots \mid B_{m} \end{bmatrix},$$

the total rowsum of the  $B_i$ 's must be  $\overline{0}$  if  $t \neq 0$ , or  $\overline{1}$  if t = 0.

くぼう くほう くほう

- CLAIM: there are enough *k*-blocks for the construction to succeed for all k<sub>0</sub> ≤ 2<sup>k-1</sup> − 1.
- Example (k = 4):  $3 \le k_0 \le 15$ , e.g.,  $k_0 = 7$ :

$$\mathcal{D}_M = \begin{bmatrix} I_4 \mid A \end{bmatrix} \qquad A = A' = \begin{bmatrix} 1 & & \\ & 1 & \\ & & 1 \\ 1 & 1 & 1 \end{bmatrix}$$

 For larger k<sub>0</sub>, take complementary sets with a change of basis:

In general:  $C_{\alpha_1,\alpha_2,...,\alpha_t} \subseteq Z_2^k$  is the set of cyclic permutations of a weight *t* column with  $\alpha_i$  ZEROES between the *i*th and (i + 1)st ONES (counting cyclically).

Using this notation,

$$Z_2^4 - \{\overline{0}\} = \begin{bmatrix} I_4 & | & C_{0,2} & | & C_{1,1} & | & C_{0,0,1} & | & \overline{1} \end{bmatrix},$$
  
Continuing our example, the complement of  $\underbrace{[I_4 | A']}_{k_0 = 7}$  is

$$\begin{bmatrix} A'' & |C_{0,0,1}| & \overline{1} \end{bmatrix}$$
 where  $A'' = C_{0,2} \cup C_{1,1} - A'.$ 

With the change of basis  $I_4 \leftrightarrow C_{0,0,1}$  (and columnwise reordering), we obtain a dependent set for  $k_0 = 15 - 7 = 8$ , namely

$$\underbrace{\begin{bmatrix} I_4 & | A'' & | \overline{1} \end{bmatrix}}_{k_0=8}.$$

In this way, we obtain dependent sets of all remaining larger sizes

$$8 = 2^{k-1} \le k_0 \le 2^k - 4 = 12.$$

・ロト ・ 理 ト ・ ヨ ト ・

Concluding claims:

- the foregoing constructions can be systematized to produce canonical, sparse generating matrices for every partition type;
- they can be adapted to actions with positive orbit-genus,
   i.e., branch data (h; R'), h > 0;
- they can be extended to Z<sup>k</sup><sub>p</sub> actions, for arbitrary primes p; the key is to consider dependent sets in the projective geometries

 $\mathsf{PG}_{k-1}(F_{\rho}),$ 

where  $F_p$  is the field with *p* elements.
